TABLE OF CONTENTS

LIST OF ACRONYMS x

1.0 INTRODUCTION 1
- 1.1 Site Background 1
- 1.2 Phase I Site Characterization Objectives 2

2.0 SITE GEOLOGY AND HYDROGEOLOGY 4
- 2.1 Site Stratigraphy 4
  - 2.1.1 Glacial Outwash and Alluvium 4
  - 2.1.2 Glacial Till 5
  - 2.1.3 Bedrock 5
- 2.2 Hydrogeology from Phase I Site Characterization Activities 6
- 2.3 Site Monitoring Wells 7
- 2.4 Site Surface Water Features 8

3.0 SCOPE OF WORK 12
- 3.1 Groundwater Gauging 12
- 3.2 Long Term Elevation Monitoring with Pressure Transducers 12
- 3.3 Groundwater Sampling 13
  - 3.3.1 Round 1 Groundwater Sampling – September 2016 14
  - 3.3.2 Round 2 Groundwater Sampling – December 2016 14
  - 3.3.3 Round 3 Groundwater Sampling – March 2017 14
  - 3.3.4 Round 4 Groundwater Sampling – June 2017 15
  - 3.3.5 Groundwater Sampling Analytical Methods 15
- 3.4 Surface Water Sampling 16
  - 3.4.1 Pre-Round 1 Surface Water Sampling – June 2016 17
  - 3.4.2 Round 1 Surface Water Sampling – September 2016 17
  - 3.4.3 Round 2 Surface Water Sampling – December 2016 18
  - 3.4.4 Round 3 Surface Water Sampling – March 2017 18
  - 3.4.5 Round 4 Surface Water Sampling – June 2017 18
  - 3.4.6 Surface Water Sampling Analytical Methods 19
- 3.5 Surface Water Elevation Monitoring 20
- 3.6 Surface Water Discharge Monitoring 21
- 3.7 Slug Testing 21
  - 3.7.1 Pneumatic Slug Testing 22
  - 3.7.2 Mechanical Slug Testing 22
- 3.8 Field Modifications 23
- 3.9 Investigation Derived Waste Management 23

4.0 GROUNDWATER INVESTIGATION RESULTS 25
- 4.1 Groundwater Elevations/Potentiometric Surfaces and Flow Patterns 25
- 4.2 Long Term Elevation Trends from Pressure Transducer Data 30
- 4.3 Groundwater Quality 31
  - 4.3.1 Field Parameters 32
    - 4.3.1.1 Monitoring Well pH 32
  - 4.3.2 Overview of Groundwater Quality based on Laboratory Analytical Results 34
    - 4.3.2.1 Cyanide in Groundwater 35

4.3.2.2 Fluoride in Groundwater 37
4.3.2.3 Metals in Groundwater 37
4.3.2.4 VOCs and SVOCs in Groundwater 39
4.3.2.5 General Chemistry in Groundwater 39
4.4 Seasonal Variability of Concentrations in Groundwater Samples 40
4.5 Slug Testing Results 41
4.5.1 Slug Test Analysis Methods, Inputs, and Assumptions 41
4.5.2 Slug Test Analysis Results 43

5.0 SURFACE WATER MONITORING AND QUALITY RESULTS 45
5.1 Surface Water Discharge Monitoring 45
5.2 Surface Water Quality 48
5.2.1 Field Parameters 48
5.3 Overview of Surface Water Quality from Laboratory Data 48
5.3.1 Cyanide in Surface Water 50
5.3.2 Fluoride in Surface Water 52
5.3.3 Metals in Surface Water 53
5.3.4 VOCs, SVOCs in Surface Water 53
5.3.5 PCBs and Pesticides in Surface Water 54
5.3.6 General Chemistry in Surface Water 54
5.4 Seasonal Variability of Concentrations in Surface Water Samples 55

6.0 GEOCHEMICAL EVALUATION 56
6.1 Piper Plots and Stiff Diagrams 56
6.2 Geochemical Modeling 57

7.0 PROJECT DATA VERIFICATION AND VALIDATION SUMMARY OF FINDINGS 58
7.1 Summary of Data Verification and Validation Results 60
7.2 Evaluation of Method Detection Limits 62

8.0 SUMMARY OF FINDINGS AND CSM REVIEW 65
8.1 Discussion of COPCs 65
8.1.1 Groundwater 65
8.1.2 Surface Water 66
8.2 Discussion of Potential Source Areas 67
8.2.1 Groundwater 67
8.2.2 Surface Water 68
8.3 Migration of COPCs from Source Areas 70
8.3.1 Groundwater 70
8.3.2. Surface Water 71

VISL	Vapor Intrusion Screening Levels
VOC	Volatile Organic Compounds

1.0 INTRODUCTION

Roux Associates, Inc. (Roux Associates), on behalf of Columbia Falls Aluminum Company, LLC (CFAC), has prepared this Groundwater and Surface Water Data Summary Report (GW/SW Data Summary Report) as part of the ongoing Remedial Investigation/Feasibility Study (RI/FS) of the CFAC facility located in Flathead County, Montana (hereinafter, "the Site"). The RI/FS is being conducted pursuant to the Administrative Settlement Agreement and Order on Consent (AOC) dated November 30, 2015, between CFAC and the United States Environmental Protection Agency (USEPA) (Comprehensive Environmental Response, Compensation, and Liability Act [CERCLA] Docket No. 08-2016-0002).

The purpose of this GW/SW Data Summary Report is to summarize the results of the groundwater and surface water investigations that were completed between September 2016 and July 2017 as part of the Phase I Site Characterization Scope of Work. The Phase I Site Characterization Scope of Work is documented in the RI/FS Work Plan (Roux Associates, 2015a), the Phase I Site Characterization Sampling and Analysis Plan (Phase I SAP [Roux Associates 2015b]), and the Phase I Site Characterization Sampling and Analysis Plan Addendum (Phase I SAP Addendum, [Roux Associates, 2016a]). The results of the Phase I Site Characterization field activities, including a summary of the first round of the groundwater and surface water investigations, was provided in the Phase I Site Characterization Data Summary Report (Phase I Data Summary Report [Roux Associates, 2017a]).

The work described in this GW/SW Data Summary Report was completed in general accordance with the "Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA" (USEPA, 1988) as well as other appropriate USEPA and Montana Department of Environmental Quality (MDEQ) guidance; and the substantive RI/FS requirements of the National Contingency Plan (40 CFR 300) (USEPA, 1994).

1.1 Site Background

The Site is located at 2000 Aluminum Drive near Columbia Falls, Flathead County, Montana. The Site is approximately 2 miles northeast from the center of Columbia Falls and the Site is accessed by Aluminum Drive via North Fork Road (County Road 486). The boundaries of the Site were defined in the RI/FS Work Plan (Roux Associates, 2015a) and are depicted in Figure 1.

The Site consists of approximately 1,340 acres bounded by Cedar Creek Reservoir to the north, Teakettle Mountain to the east, Flathead River to the south, and Cedar Creek to the west.

The Site was operated as a primary aluminum reduction facility (commonly referred to as an aluminum smelter) from 1955 until 2009. The facility began with two potlines in 1955 and an annual capacity of 67,500 tons per year (using 120 pots per potline). A third potline was added in 1965, and the fourth and fifth potline were added 1968, increasing total aluminum production capacity at the Site to 180,000 tons per year. The plant expanded to 10 pot rooms in the 1960s. Aluminum production at the Site was suspended in 2009 due to a downturn in aluminum market conditions, and CFAC announced the permanent closure of the facility in March 2015. A detailed description of the operational history at the Site was provided in Section 2.7.2 of the RI/FS Work Plan (Roux Associates, 2015a).

Buildings and industrial facilities remaining at the Site at the start of the Phase I Site Characterization included offices, warehouses, laboratories, mechanical shops, paste plant, coal tar pitch tanks, pump houses, casting garage, and the potline facility. The Site also includes seven closed landfills, one open landfill that hasn't been used since 2009, material loading and unloading areas, two closed leachate ponds, and several wastewater percolation ponds. A detailed description of each Site feature was provided in Section 3.2 of the RI/FS Work Plan (Roux Associates, 2015a). A map showing the locations of Site features is provided for reference as Figure 2 of this GW/SW Data Summary Report.

1.2 Phase I Site Characterization Objectives

The Phase I Site Characterization program was designed to identify and/or confirm source areas and associated contaminants of potential concern (COPCs) outlined in the RI/FS Work Plan (Roux Associates, 2015a), as well as provide a broad characterization of the hydrogeologic conditions and the nature and extent of contamination across the Site and around Site features. As stated in the RI/FS Work Plan (Roux Associates, 2015a), the following objectives were established for Phase I Site Characterization Program:

- Evaluate the conditions at all identified RI areas and Site features to determine which RI areas and Site features require further investigation and/or quantitative evaluation in the Baseline Risk Assessment;

- Refine the list of COPCs that require further investigation at various RI areas and Site features so lists of laboratory analyses can be reduced during subsequent phases of investigation;

- Refine the understanding of groundwater flow and groundwater quality beneath the Site, particularly in the vicinity of potential receptors;

- Develop a more detailed understanding of bedrock topography and the depths, thicknesses, and extents of the various hydrogeologic units, both of which may influence groundwater flow and the distribution of COPCs in the subsurface;

- Begin to evaluate seasonal influences on groundwater/surface water interactions and contaminant concentrations in groundwater and surface water;

- Develop data to support the preparation of the Baseline Risk Assessment Work Plan; and

- Develop data to support identification and screening of remedial technologies as part of the FS.

This GW/SW Data Summary Report summarizes the results of groundwater and surface water investigations that have been completed to achieve the Phase I Site Characterization objectives listed above.

2.0 SITE GEOLOGY AND HYDROGEOLOGY

This Section provides a summary of the Site geology observed during the Phase I Site Characterization and discusses the influence that Site geology has on hydrogeologic conditions in the subsurface beneath the Site. This Site geology section provides a framework for understanding the groundwater flow and groundwater/surface water quality data and discussion presented throughout this GW/SW Data Summary Report.

2.1 Site Stratigraphy

A summary of regional and Site geology was provided in Section 2.4 of the RI/FS Work Plan (Roux Associates, 2015a) based on previous investigations at the Site and published literature for the Kalispell Valley region. Lithology collected from soil borings completed during the Phase I Site Characterization were utilized to evaluate the stratigraphy beneath the Site. As presented in the Phase I Data Summary Report (Roux Associates, 2017a), there are three major stratigraphic units underlying the Site. The three stratigraphic units consist primarily, from land surface down, of:

- Glacial Outwash and Alluvium: A layer of glaciofluvial and alluvial coarse-grained soils, varying in vertical extent and grain size depending on vicinity to Site features (i.e., Teakettle Mountain, Flathead River, etc.);
- Glacial Till: A layer of dense, poorly sorted glacial till with interbedded deposits of glaciolacustrine clays and silts; and
- Bedrock.

Generalized hydrogeologic cross sections are provided in the Phase I Data Summary Report (Roux Associates, 2017a). Descriptions of the three stratigraphic units observed during the Phase I Site Characterization are provided in the following sections.

2.1.1 Glacial Outwash and Alluvium

The glacial outwash and alluvium layer typically contains coarse grained soils (varying amounts of sand, gravel, and cobbles) with varying degrees of sorting and with lesser amounts of fines. The glacial outwash layer is encountered at the surface across most of the Site, with recent alluvial deposits present primarily near the southern border of the Site in the vicinity of the Flathead River.

The findings described in the Phase I Data Summary Report (Roux Associates, 2017a) indicate that the glacial outwash vertical thickness appears to be relatively consistent in areas north and west of the Main Plant Area, with average thicknesses ranging from 50 to 80 feet thick. The glacial outwash north of the Main Plant Area reaches maximum vertical thickness in the areas beneath the Former Drum Storage Area, West Landfill, Wet Scrubber Sludge Pond, and Center Landfill; where thickness was typically observed to range from 125 to 150 feet. The thickness tends to decrease close to Teakettle Mountain where bedrock elevations are shallower. Near the Flathead River, the vertical extent of the alluvial deposits is approximately 100 feet thick beneath the western and south-central portion of the Site. The thickness of the alluvial deposits near the river is greatest to the area south east of the Main Plant Area, near former production wells (PW) PW-4 and PW-5 (CFMW-052 and CFMW-051, respectively), where thicknesses of greater than 150 feet were observed.

2.1.2 Glacial Till

Glacial till was observed in the subsurface across most of the Site, typically beneath the coarse-grained outwash deposits. The glacial till layer is a dense, poorly-sorted deposit, consisting of varying amounts of sand, gravel, cobbles, silt, and clay. The till was typically noted to be drier and denser than the overlying coarse-grained deposits.

The maximum vertical extent of the glacial till is unknown in the areas to the north, west, and south of the Site, as the next lithologic layer was not encountered during drilling. This indicates that the till is typically at least 200 feet thick or greater in these areas. The glacial till unit was observed to have pockets of wet, coarse grained soils interbedded in the till layer and also interbedded layers of primarily silt or primarily clay. The interbedded layers are generally not continuous and can be found scattered throughout the till layer. These interbedded layers form complex, heterogeneous conditions that likely result in interbedded zones of high and low hydraulic conductivities, which influence the overall deep groundwater flow system beneath the Site.

2.1.3 Bedrock

Based on regional geologic literature, beneath the unconsolidated glacial deposits are pre-Cambrian aged bedrock. The literature indicates that the depth to bedrock increases in a

southwestern direction across the Site, as you move away from Teakettle Mountain. This was confirmed during the Phase I Site Characterization. Bedrock was encountered in soil boring CFMW-023a, which is located in the eastern portion of the Site near Teakettle Mountain, at approximate depths of 150 feet below land surface (ft-bls). Weathered bedrock was also encountered in soil boring CFMW-008a (also located near Teakettle Mountain) at approximately 130 ft-bls, and a more competent bedrock within the same boring at approximately 245 ft-bls. Bedrock was not encountered in any of the other deep soil borings completed at the Site, indicating that depth to bedrock is greater than 300 ft-bls across most of the Site.

2.2 Hydrogeology from Phase I Site Characterization Activities

The stratigraphic units underlying the Site form a complex hydrogeologic framework that influences groundwater elevations, groundwater flow, and potential COPC migration beneath the Site. The coarse grained glacial outwash and alluvium deposits that are found above the glacial till are collectively referred to as the "upper hydrogeologic unit" at the Site. During drilling, the glacial deposits comprising the upper hydrogeologic unit were typically observed to be loose and wet when water was encountered at the water table. Based upon relatively consistent elevations at which groundwater was encountered within the upper hydrogeologic unit, and the occurrence of groundwater at all drilling locations, it appears that the unit is horizontally continuous across the investigated area. The continuity of the upper hydrogeologic unit is also confirmed by hydraulic flow directions and gradients measured during monitoring well gauging (see section 4.1) and by the geochemistry and apparent transport of COPCs observed during groundwater sampling (see section 4.3.2).

While the upper hydrogeologic unit appears to be continuous across the Site, the groundwater within the upper hydrogeologic unit appears to exist under perched water-table conditions. Perched zones have been documented to occur at various locations throughout the Kalispell Valley and have historically been referred to in regional literature as the Pleistocene perched aquifers (Konizeski et al., 1968). The perched conditions are supported by the lithology, and also the rapid and pronounced response to precipitation/seasonal changes that are observed around the landfill and Main Plant Areas, as described in Sections 4.1 and 4.2. The saturated thickness of the upper hydrogeologic unit varies across the Site depending upon the depth to underlying glacial till (see below) and proximity to Teakettle Mountain. Saturated thickness was observed to be less

near Teakettle Mountain, when compared to areas beneath the landfills and west of the landfills. This was confirmed during monitoring well gauging (See section 4.1 below), when it was observed that some of the wells near Teakettle Mountain became dry in late summer/early fall due to seasonal fluctuation in groundwater levels.

During drilling, the glacial tills found below the upper hydrogeologic unit were typically characterized as containing a higher percentage of fines, and as denser and drier, than the overlying outwash and alluvium deposits. The till deposits were often characterized as stiff and, moist or dry; in contrast to the overlying outwash and alluvium that was typically characterized as loose and wet. These observations indicate that the till deposits likely have a lower hydraulic conductivity than the overlying outwash and alluvium deposits. This is supported by observations during monitoring well development, where the new, deep wells screened within the tills typically yielded much less water than wells screened in the outwash deposits. This is also supported by slug testing data which was collected from monitoring wells screened in the glacial till. As described in Section 4.5, slug testing data indicates that the minimum, maximum, and geometric mean hydraulic conductivities measured in the glacial till were lower than the upper hydrogeologic unit.

Based upon the conceptual Site model, bedrock is considered to define the bottom of the hydrogeologic system beneath the Site.

2.3 Site Monitoring Wells

As part of the Phase I Site Characterization field activities, 44 new monitoring wells were installed at the Site, including 28 monitoring wells installed slightly beneath the water table within the upper hydrogeologic unit and 16 monitoring wells installed deeper within the glacial tills. The new monitoring well locations were installed to supplement the existing monitoring well network at the Site to support further evaluation of groundwater quality in potential source areas and in areas that have not previously been monitored, while also helping to refine the understanding of Site groundwater flow. Plate 1 shows the locations of all monitoring wells at the Site. Table 1 summarizes the construction details for the monitoring wells at the Site.

Upper hydrogeologic unit monitoring wells were typically installed with the top of the screened interval located approximately 5 to 10 feet below the observed water table at the time of drilling to account for seasonal fluctuations in groundwater elevations. Deep monitoring wells were installed to evaluate the vertical extent of COPCs in groundwater and to evaluate groundwater flow within deeper hydrogeologic units. The screened intervals of the deep wells were determined by Roux Associates personnel based on field observations made during drilling, and were typically set below the first low-permeability unit observed during drilling. In locations where a low permeability unit was not encountered, a spacing of 25 feet or greater was placed between the monitoring wells installed beneath the water table and the deeper wells. In locations where bedrock was encountered close to the water table, the deeper well was placed immediately above the bedrock.

Construction details for all new monitoring wells are provided in well logs in the Phase I Data Summary Report (Roux Associates, 2017a). Following surface completion, all newly installed monitoring wells, as well as existing monitoring wells, were surveyed by Sands Surveying Inc. (Sands Surveying) of Kalispell, Montana for horizontal (North American Datum [NAD] 83) and vertical (North American Vertical Datum [NAVD] 88) coordinates within the Montana State Plane Coordinate System (FIPS2500). Survey data is included on Table 1.

2.4 Site Surface Water Features

The Site is located within the Flathead River watershed. The Site is bordered by surface water features on each side, including the Flathead River to the south, Cedar Creek to the west, and Cedar Creek Reservoir Overflow Ditch to the east. Figure 2 depicts the locations of these surface water features. The below sections provide a summary of the surface water features at the Site.

2.4.1 Flathead River

The North Fork of the Flathead River originates in British Columbia and the Middle Fork of the Flathead River originates in the Bob Marshall Wilderness located south of Glacier National Park. The North Fork and the Middle Fork border Glacier National Park on the western and southern boundaries, respectively, and flow south of Glacier National Park where they meet the South Fork of the Flathead River at the entrance of Badrock Canyon, and the river is then called the Flathead River. The Flathead River flows west through Badrock Canyon towards Columbia Falls, where it

eventually flows past the Site. After passing the Site, the River flows south towards Flathead Lake (Ecology and Environmental, Inc [EE], 1988).

As of January 2017, the United States Geological Survey (USGS) currently maintains three active gauging stations on the Flathead River in the general vicinity of the Site. The closest station is located approximately three miles southwest of the Site near Columbia Falls (USGS Station #12363000). Two stations are located approximately 10 miles north/northeast of the Site: the station on the North Fork of the Flathead River and the Middle Fork station immediately west of Glacier National Park (USGS Station #s 12355500 and 12358500, respectively). Discharge data downloaded from the USGS gauging station closest to the Site is provided in Appendix A and is discussed in Section 5.1.

In terms of interaction with the groundwater system, published literature indicates the Spring high flows in the Flathead River result in the Flathead River recharging groundwater and acting as a losing stream (Konizeski et al., 1968). As described in the Phase I Data Summary Report (Roux Associates, 2017a), the water level data collected in August 2016 and November 2016 (a low flow period) indicate that adjacent to the Site, the Flathead River is receiving groundwater from the upper hydrogeologic unit beneath the Site.

2.4.2 Cedar Creek

Cedar Creek originates north of the Site in the Whitefish mountains and flows approximately three miles southwest towards the City of Columbia Falls. Based upon the flat topography of the portion of the Site located within one-half mile of Cedar Creek, there is little potential for surface water runoff into Cedar Creek from the Main Plant Area or surrounding former operational areas within the Site. In addition, the elevation of Cedar Creek is higher than groundwater elevations within the Site, indicating that Cedar Creek is a perched or losing stream rather than a gaining stream (i.e., Site groundwater does not discharge into Cedar Creek).

2.4.3 Cedar Creek Reservoir Overflow Ditch

The Cedar Creek Reservoir Overflow Ditch runs from the Cedar Creek Reservoir north of the Site, to the Flathead River. The Cedar Creek Reservoir Overflow Ditch runs alongside the Sanitary

Landfill, Center Landfill, the southern Asbestos Landfill, and the East Landfill and Leachate Collection Ponds before discharging into the Flathead River.

The Cedar Creek Reservoir Overflow Ditch flows intermittently in the spring and is used to regulate flow for Cedar Creek and levels within the reservoir. Based upon proximity and land surface topography, some surface water runoff from the eastern side of the Site, originating from the vicinity of the East and Sanitary Landfills, may flow to the Cedar Creek Reservoir Overflow Ditch. Similar to Cedar Creek, the elevation of Cedar Creek Reservoir Overflow Ditch is higher than surrounding groundwater elevations within the Site, indicating that the Cedar Creek Reservoir Overflow Ditch may be a losing stream.

2.4.4 South Percolation Ponds

The South Percolation Ponds are a series of three ponds located on the south end of the Site, adjacent to the Flathead River. The ponds are 2.4, 1.2 and 6.6 acres in size (from west to east) forming a total of 10.2 acres, and are connected in series. Water is discharged into the South Percolation Ponds system from a concrete pipe located on the west end of the pond system. From the pipe, water flows into the ponds through an unlined ditch. Historically, the South Percolation Ponds received water from various operations within the Main Plant area. Currently, only stormwater is discharged into the South Percolation Ponds.

2.4.5 North Percolation Ponds

The North Percolation Ponds consists of two interconnected percolation ponds (the North-East Percolation Pond and the North-West Percolation Pond). The North-East Percolation Pond is approximately 2.0 acres in size and was constructed in 1955. The North-East Percolation Pond is currently operational and a discharge point for stormwater drainage. This percolation pond received discharges from various operations within the Main Plant area until manufacturing ceased in 2009. Based on the aerial photography review, the exact size and shape of the North-East Percolation Pond changed slightly over time.

The North-West Percolation Pond is approximately 8 acres in size. The North-West Percolation Pond receives water from the North-East Percolation Pond. The two ponds were connected by an approximately 1,440-foot-long unlined ditch.

2.4.6 Northern Surface Water Feature

The Northern Surface Water Feature is a seasonal ponding area located between Cedar Creek and the Cedar Creek Reservoir Overflow Ditch, just south of the Industrial Landfill. Site reconnaissance indicated the area is seasonally fed in the spring and early summer by at least two groundwater seep areas located north of the main ponding area in the southern portion of the feature. Further reconnaissance later in September 2016 show the feature to be void of surface water. It is believed that during the spring, the snowmelt and increased seasonal precipitation creates a localized elevated or perched water table which feed the seeps. The substrate of the feature is predominantly grass covered with areas of channelization which help direct the groundwater from the seep area to the feature.

3.0 SCOPE OF WORK

The Scope of Work summarized in this GW/SW Data Summary Report is a subset of the of work described in the RI/FS Work Plan (Roux Associates, 2015a) and the Phase I SAP (Roux Associates, 2015b). Modifications to the Scope of Work were documented in field modifications throughout the Phase I Site Characterization field activities. The Scope of Work included the following tasks:

- Four rounds of Site-wide monitoring well gauging to evaluate Site-wide groundwater elevations and flow directions;
- Installation of pressure transducers to monitor long-term groundwater elevations at selected monitoring well locations;
- Four rounds of groundwater sampling to evaluate seasonal changes in groundwater quality;
- Four rounds of surface water sampling and streamflow measurements to evaluate seasonal changes in surface water quality and surface water flow; and
- Pneumatic and mechanical slug testing to evaluate hydraulic conductivity.

The following sections describe the work that was completed for each task.

3.1 Groundwater Gauging

Site-wide groundwater levels were measured by Roux Associates on August 30, 2016, November 29, 2016, March 14/15, 2017, and June 16, 2017. Groundwater level measurements were collected to provide a snapshot of the Site-wide groundwater elevations immediately prior to the start of each groundwater and surface water sampling round. Groundwater levels were collected with an electronic water-level meter capable of measuring fluid elevation within an accuracy of 0.01 feet (ft). Plate 1 shows the locations of Site monitoring wells and Table 2 provides a summary of the measurements collected on each date. Wells designated as "NM" on Table 2 were not measured due to being inaccessible.

3.2 Long Term Elevation Monitoring with Pressure Transducers

Six (6) In-Situ Level Troll 700 pressure transducers were deployed in existing monitoring wells at the Site in April 2016, prior to installation of any new monitoring wells. The transducers were installed to continuously collect groundwater elevation data in various areas of the Site and around different Site features, with the objective of developing an understanding of groundwater elevation

fluctuations in response to precipitation events and longer term seasonal trends at the Site. The monitoring wells equipped with pressure transducers in April 2016 included CFMW-001, 007, 020, and 049 (screened in the upper hydrogeologic unit), and CFMW-044b and 056 (screened below the upper hydrogeologic unit). The pressure transducer in CFMW-007 was removed in June 2016 and installed in monitoring well CFMW-003, which is also screened in the upper hydrogeologic unit.

In March 2017, the six pressure transducers were relocated to monitoring wells CFMW-016, 016a, 019, 019a, 053, and 053a. These well locations were selected to evaluate groundwater elevation fluctuations in nested monitoring wells (i.e., well locations with monitoring wells screened in the upper hydrogeologic unit and below the upper hydrogeologic unit) around the West and Center Landfills, and near the Flathead River downgradient of the landfill area.

Pressure transducer data were downloaded multiple times throughout the field activities, typically coinciding with monitoring well gauging activities. Hydrographs for each location displaying groundwater elevation over time and precipitation from Glacier National Park Airport (Kalispell, MT) are provided in Appendix B. In addition to the data collected with the six deployed pressure transducers, Roux Associates also reviewed data collected by the Montana State Bureau of Mines from a pressure transducer that was deployed in existing monitoring well CFMW-007/TW-3 (identified ID 87873 in the Montana Bureau of Mines and Geology [MBMG] website well database [MBMG, 2017]).

3.3 Groundwater Sampling

Roux Associates and Hydrometrics (Roux Associates' subcontractor) performed groundwater sampling during four separate sampling events between September 2016 and June 2017. Each round of sampling was approximately two weeks in duration. Groundwater samples were collected using the methods described in the USEPA guidance document titled "Ground Water Sampling Procedure, Low Stress (Low Flow) Purging and Sampling" (USEPA, 2010) and in accordance with the applicable Roux Associates' Standard Operating Procedures (SOPs) provided in the Phase I SAP (Roux Associates, 2015b).

During groundwater sampling, a water quality meter was used to monitor water quality indicator parameters such as pH, conductivity, dissolved oxygen (DO), oxidation reduction potential (ORP), temperature, and turbidity. The field parameters and information about each sample were recorded on monitoring well sampling field data sheets which are included as Appendix C. The following sections further describe each groundwater sampling round.

3.3.1 Round 1 Groundwater Sampling – September 2016

The first round of groundwater sampling was conducted from September 9, 2016 through September 21, 2016 (Round 1) with samples being collected from a total of 60 monitoring wells. Groundwater samples were not collected from four monitoring wells (CFMW-016, CMFW-017, CFMW-018, and CFMW-025) that were dry during the sampling event. Samples collected during the Round 1 September 2016 groundwater sampling event are summarized in Table 3.

3.3.2 Round 2 Groundwater Sampling – December 2016

The second round of groundwater sampling was conducted from December 5, 2016 through December 19, 2016 (Round 2) with samples being collected from a total of 58 monitoring wells. A total of six monitoring wells (CFMW-002, CFMW-016, CFMW-017, CFMW-018, CFMW-025, and CFMW-042) were unable to be sampled due to either dry conditions or insufficient water within the well to collect a sample during the sampling event. Samples collected during the Round 2 December 2016 groundwater sampling event are summarized in Table 3.

3.3.3 Round 3 Groundwater Sampling – March 2017

The third round of groundwater sampling was conducted from March 20, 2017 through March 30, 2017 (Round 3) with samples being collected from 61 monitoring wells. Groundwater samples were not collected from two monitoring wells (CFMW-042 and CFMW-053) due to dry well conditions or insufficient water within the well during the sampling event. Additionally, a sample was not collected from monitoring well CFMW-025 because it was inaccessible due to being damaged by a snow plow. Samples collected during the Round 3 March 2017 groundwater sampling event are summarized in Table 3.

3.3.4 Round 4 Groundwater Sampling – June 2017

The fourth round of groundwater sampling was conducted from June 19, 2017 through June 29, 2017 (Round 4) with samples being collected from 63 monitoring well locations. A sample was not collected from monitoring well CFMW-025 which did not contain sufficient water for sampling during the sampling event. Additionally, two monitoring wells (CFMW-025 and CFMW-053) that were damaged from the snow plow during the winter were repaired prior to the sampling. Both wells were resurveyed by Sands Surveying on June 13, 2017. Samples collected during the Round 4 June 2017 groundwater sampling event are summarized in Table 3.

3.3.5 Groundwater Sampling Analytical Methods

All groundwater samples from all four sampling events were analyzed for the following analytical methods as noted in the RI/FS Work Plan (Roux Associates, 2015a) and Phase I SAP (Roux Associates, 2015b):

- Dissolved Target Analyte List (TAL) metals via USEPA Methods 6020A / 7470A;
- Total cyanide via USEPA Method 335.4;
- General chemistry including fluoride via USEPA Method 300, alkalinity via Method SM2320B, and hardness via Method 2340B;
- Nutrients including chloride and sulfate via USEPA Method 300.0, nitrate and nitrite (as nitrogen) via USEPA Method 353.2, ammonia nitrogen via USEPA Method 350.1/350.3, and orthophosphate as phosphorus via USEPA Method 365.1; and
- Total dissolved solids (TDS) and total suspended solids (TSS) via Methods SM 2540C/D.

The groundwater samples collected adjacent to potential source areas, as noted in the RI/FS Work Plan (Roux Associates, 2015a) and Phase I SAP (Roux Associates, 2015b), also included the following additional analytes:

- Target Compound List (TCL) volatile organic compounds (VOCs) via USEPA Method 8260B; and
- TCL semivolatile organic compounds (SVOCs) via USEPA Method 8270D.

Based on review of the groundwater quality data from Rounds 1 and 2 of sampling (September 2016 and December 2016), and prior to Round 3 (March 2017), Field Modification #9 was submitted to USEPA (described in Section 3.8) requesting the addition of free cyanide analysis via

USEPA method 9016 for the third round of sampling at all locations where total cyanide was detected in either Round 1 or Round 2. As such, a total of 44 out of the 64 existing monitoring wells located at the Site were analyzed for free cyanide during the third groundwater sampling event.

At a project meeting held on April 19, 2017, USEPA, MDEQ, CFAC, Roux Associates, and CDM Smith (USEPA third-party oversight) discussed the sampling results from Rounds 1 through 3 and agreed to add additional analyses to the Round 4 sampling. During Round 4 in June 2017, the 63 monitoring wells sampled were analyzed for the following additional analyses:

- Total TAL metals via USEPA Methods 6020A / 7470A;
- Dissolved total cyanide via USEPA Method 335.4; and
- Dissolved fluoride via USEPA Method 300.0.

Additionally, at all locations where total cyanide was detected in Rounds 1, 2, or 3, groundwater samples were analyzed for both free cyanide and dissolved free cyanide via USEPA Method 9016 during Round 4. This included 51 monitoring wells, which was an increase from the 44 monitoring wells that were analyzed for free cyanide in Round 3.

3.4 Surface Water Sampling

Roux Associates performed surface water sampling during four sampling events between September 2016 and June 2017. Each surface water sampling event was generally performed over a one-week period, and the four sampling events coincided with the groundwater sampling events. During each sampling event, Roux Associates collected surface water samples from Site surface water features that were observed to contain water during the respective sampling event. In addition to the four sampling events, select surface water locations were sampled in June 2016, prior to the first round of sampling, because it was determined during the initial Site reconnaissance that some surface water areas could dry out over the summer months.

Surface water samples were collected as grab samples from within the Site feature by Roux Associates personnel. Samples were collected at a depth of approximately 60 percent of the total water column depth. The maximum water depth at any surface water sample location was approximately two feet. However, during the initial Site reconnaissance, several surface water

sample locations along the Flathead River were deemed inaccessible by foot due to the presence of forested areas and limited bank/shoreline for traversing. In accordance with Field Modification #8 (described in Section 3.8), Roux Associates collected surface water samples from Flathead River with the use of a boat provided by Kennedy/Jenks Consulting (subcontractor to Roux Associates). A captain representative of Kennedy/Jenks Consulting steered the boat through the river, and surface water samples were collected from the boat by taking a grab sample directly from the waterbody using the sample collection container for each analysis.

As part of the sample collection activities within the surface water bodies, the surface water was field screened with a water quality meter to evaluate water quality parameters; including: temperature, conductivity, pH, turbidity, DO, and ORP. The water quality meter was placed directly in the surface water body and monitored until stable readings were observed. The readings were recorded on a field datasheet and the location within the surface water body was logged with GPS technology with sub-meter accuracy. Surface water sample field data sheets are included as Appendix C. Surface water sampling locations are shown on Plate 2 and are summarized on Table 4. Each surface water sampling event is further described in the next sections.

3.4.1 Pre-Round 1 Surface Water Sampling – June 2016

On June 6, 2016 and June 7, 2016, ten surface water samples were collected from selected surface water bodies that were anticipated to dry out over the summer months as part of the pre-Round 1 surface water investigation. These locations included three locations in the South Percolation Ponds, five locations in the Cedar Creek Reservoir Overflow Ditch, and two locations in the Northern Surface Water Feature. The North-West and North-East Percolation ponds were also inspected during this time period for potential sampling but no surface water was present and therefore, no surface water samples were collected from these locations. Samples collected during the pre-Round 1 June 2016 surface water sampling event are summarized in Table 4.

3.4.2 Round 1 Surface Water Sampling – September 2016

The first surface water sampling event occurred from August 29, 2016 to September 16, 2016 and included sampling of the 12 remaining surface water locations not sampled during the June 2016 pre-Round 1 investigation. During Round 1, samples were collected from within the Flathead

River, the Backwater Seep Sampling Area, and Cedar Creek. Similar to the June 2016 sampling event, surface water samples were not collected within the North-West and North-East Percolation ponds due to an absence of surface water. Samples collected during the Round 1 surface water sampling event are summarized in Table 4.

3.4.3 Round 2 Surface Water Sampling – December 2016

The second surface water sampling event occurred from November 30, 2016 to December 2, 2016, and also included an additional day of sampling on December 20, 2016. During Round 2, 17 surface water locations were sampled, including one location in Cedar Creek (CFSWP-025) that was added to the Scope of Work as an opportunity sample (collected on December 20, 2016), based on evaluation of the Round 1 data. During the Round 2 sampling event, seven proposed surface water sampling locations were not sampled due to being dry. These seven locations were within the Northern Surface Water Feature, North-West and North-East Percolation Ponds, and the Cedar Creek Reservoir Overflow Ditch. Samples collected during the Round 2 surface water sampling event are summarized in Table 4.

3.4.4 Round 3 Surface Water Sampling – March 2017

The third round of surface water sampling occurred from March 13, 2017 through April 4, 2017. Thirteen surface water samples were collected from March 13, 2017 to March 16, 2017. During this period, the remainder of the surface water features were covered with snow due to accumulation over the winter months and were either inaccessible or no running/ponded water was observed within these sampling locations. Eleven surface water locations were sampled on April 3, 2017 and April 4, 2017, after snow melted and the locations were accessible for sampling. One surface water point (CFSWP-024) located within the North-East Percolation Pond was not sampled during the third round of sampling due to dry conditions. Samples collected during the Round 3 surface water sampling event are summarized in Table 4.

3.4.5 Round 4 Surface Water Sampling – June 2017

The fourth sampling event occurred from June 12, 2017 to June 15, 2017. Round 4 of sampling included the collection of 23 surface water samples. Two sampling locations were found to contain no water during Round 4, CFSWP-022 and CFSWP-023. These sampling points are located within the Northern Surface Water Feature and the North-West Percolation Pond,

respectively. Samples collected during the Round 4 surface water sampling event are summarized in Table 4.

3.4.6 Surface Water Sampling Analytical Methods

All surface water samples from the four sampling events were analyzed for the following analytical methods as noted in the RI/FS Work Plan (Roux Associates, 2015a) and Phase I SAP (Roux Associates, 2015b):

- Total recoverable TAL metals via USEPA Methods 6020A / 7470A;
- Total cyanide via USEPA Method 335.4;
- General chemistry including fluoride via USEPA method 300, alkalinity via Method SM2023B, and hardness via USEPA Method 200.7;
- Nutrients including chloride and sulfate via USEPA method 300.0, nitrate and nitrite (as nitrogen) via USEPA Method 353.2, ammonia nitrogen via USEPA Method 350.1 / 350.3, and orthophosphate as phosphorous via USEPA Method 365.1; and
- TDS and TSS via Methods SM 2540C/D.

The initial surface water samples collected during pre-Round 1 within the South Percolation Ponds were also analyzed for the following additional analytes:

- TCL VOCs via USEPA Method 8260;
- TCL SVOCs via USEPA Method 8270;
- TCL polychlorinated biphenyls (PCBs) via USEPA Method SW8082; and
- TCL pesticides via USEPA Method 8081.

Similar to groundwater, Roux Associates evaluated the surface water quality data from the first and second rounds of sampling (September 2016 and December 2016). Based on review of the data, and prior to Round 3, Field Modification #9 was submitted to USEPA (described in Section 3.8) requesting the addition of free cyanide analysis via USEPA Method 9016 for the third round of sampling at all locations where total cyanide was detected in either Round 1 or Round 2. A total of seven out of 25 possible locations were analyzed for free cyanide during the third sampling event. These locations included three samples in the Backwater Seep Sampling Area,

two samples in Cedar Creek, and one sample each in the Flathead River and the South Percolation Ponds.

At the project meeting held on April 19, 2017, USEPA, MDEQ, CFAC, Roux Associates, and CDM Smith also discussed the surface water sampling results from Rounds 1 through 3 and agreed to add additional analyses to the Round 4 sampling event. During Round 4 in June 2017, the surface water samples were also analyzed for the following additional analyses:

- Dissolved TAL metals via USEPA Methods 6020A / 7470A;
- Dissolved total cyanide via USEPA Method 335.4;
- Dissolved fluoride via USEPA Method 300.0;
- Sulfide via USEPA Method SM 4500_S2_F; and
- Dissolved Organic Carbon (DOC) via USEPA Method 9060A.

Additionally, at all seven locations where total cyanide was detected in Rounds 1, 2, or 3, surface water samples were analyzed for both free cyanide and dissolved free cyanide via USEPA Method 9016.

3.5 Surface Water Elevation Monitoring

Surface water elevations at USGS station #12363000 (located in the Flathead River immediately down river of the Site as described in Section 5.1) were reviewed throughout the Phase I Site Characterization field activities to understand seasonal changes in the Flathead River conditions and to evaluate river conditions prior to sampling events. Data from the USGS station was downloaded and graphed in Appendix A.

A temporary staff gauge was also installed within the Flathead River to enable measurement of river level conditions immediately adjacent to the Site. The temporary staff gauge was surveyed by Sands Surveying and staff gauge readings were recorded in conjunction with each groundwater level gauging event. Following the reading from the staff gauge during the third round of sampling, Roux workers observed that the staff gauge was damaged and bent due to strong water flow and ice debris within Flathead River. A new staff gauge was installed on June 13, 2017, prior to the Round 4 Site-wide gauging event conducted on June 16, 2017. The newly installed

staff gauge was surveyed by Sands Surveying on the same day of installation. Surface water elevations from the staff gauge are included Table 2 and discussed in Section 5.1.

3.6 Surface Water Discharge Monitoring

As part of the surface water sampling events, the discharge of Cedar Creek and the Cedar Creek Drainage Overflow were measured utilizing a mechanical current-meter. The stream channel cross section was divided into equal vertical subsections. In each subsection, the area was calculated by measuring the width and depth of the subsection, and the water velocity was determined using a current flow meter. The discharge in each subsection was computed by multiplying the subsection area by the measured velocity and the total discharge was determined by summing the discharge of each subsection. Stream discharge calculations for each sampling event are provided in Appendix D.

3.7 Slug Testing

Roux Associates conducted slug testing on the new 2-inch diameter monitoring wells installed as part of the Phase I Site Characterization. The slug tests were performed following the fourth groundwater and surface water sampling event, from July 10, 2017 to July 27, 2017. The slug testing program was conducted to determine hydraulic conductivity in the subsurface across the Site and to evaluate the *in situ* permeability contrast between various hydrogeologic units beneath the Site.

Slug tests were performed on 43 of the 44 newly installed Phase I Site Characterization monitoring wells. One monitoring well (CFMW-018) did not have adequate water to conduct a slug test, and therefore, was not tested. Slug tests were performed via one of two methods: pneumatic or mechanical slug testing. The pneumatic slug test method was the preferred testing method due to the level of accuracy able to be achieved in high conductivity settings. Pneumatic slug testing methods were used at locations where the entire length of screen of the monitoring well was submerged beneath the level of standing water in the well. If the water level was below the top of the screen, mechanical slug testing was performed.

Four tests were generally completed at each location: two 1-foot displacement tests; and two 2-foot displacement tests. Two tests were conducted at each displacement level to assess the

reproducibility of the data for consecutive tests. As outlined in the Field Modification #11 (described is Section 3.8), if water levels did not return to static or near static conditions within one hour of the first test, a test at the second displacement depth (i.e., two-foot displacement) was not completed. Slug testing field data sheets are provided in Appendix C. Slug testing data and analysis is discussed in Section 4.5. The remainder of this Section describes the different slug testing methods.

3.7.1 Pneumatic Slug Testing

Pneumatic slug tests were performed on 35 of the 43 wells. All pneumatic tests were conducted in accordance with the procedures outlined in the SOP titled "Standard Operating Procedure 4.8 for Conducting a Pneumatic Slug Test." Pneumatic slug tests were conducted using compressed air as the displacing (slug) volume. The water column within the well casing was depressed by increasing the air pressure in the casing above the water column. When the water level was depressed to a predetermined level and the air pressure stabilized within the test interval, the air pressure within the well casing was rapidly released. The instantaneous release of air pressure from the well casing initiated a pneumatic slug withdrawal test, which was recorded using a pressure transducer data logger.

3.7.2 Mechanical Slug Testing

Mechanical slug tests were performed on seven wells. Additionally, one well (CFMW-002) had the 1-foot test completed pneumatically and the 2-foot test completed mechanically due to the water level in the well dropping below the screen between the two tests. All mechanical tests were conducted in accordance with the procedures outlined in the SOP titled "Standard Operating Procedure 4.9 for Conducting a Mechanical Slug Test." Mechanical slug tests were conducted within using a solid cylinder (slug). Due to the fact that mechanical slug tests were being performed on wells screened near the water table, the testing was limited to "slug-out" tests. As part of the "slug-out test", the water column within the well casing was decreased by rapidly removing the solid slug from the water column. All changes in water levels were recorded using a pressure transducer data logger.

3.8 Field Modifications

A total of three field modifications related to evaluation of groundwater and/or surface water were implemented in consultation with the USEPA throughout the course of the Phase I Site Characterization, including:

- Modification #8 (August 30, 2016) – Several surface water and sediment sample locations along the Flathead River were determined to be inaccessible by foot due to the presence of forested areas and limited bank/shoreline for traversing; therefore, these sample locations were accessed with the use of a boat for all four rounds of sampling.

- Modification #9 (March 2, 2017) – Free cyanide analysis was added to the sampling Scope of Work for all monitoring well and surface water locations where there were detections of cyanide above the method detection limit in Rounds 1 and 2.

- Modification #11 (June 12, 2017) – Pneumatic and mechanical slug testing of newly installed monitoring wells were added to the Scope of Work.

Modifications were memorialized in Record of Modification forms submitted to the USEPA for approval prior to implementing the change. Executed Record of Modification forms are included as Appendix E. In addition to the three modifications described above, additional sampling analyses were added to the fourth round of surface water and groundwater sampling following the USEPA meeting in April 2017 as described in Sections 3.3.5 and 3.4.6.

3.9 Investigation Derived Waste Management

Water investigation derived waste (IDW) that was generated during monitoring well development and the four rounds of groundwater sampling was managed onsite in accordance with the IDW Management Plan dated May 9, 2016. IDW water was stored in two 8,000-gallon frac tanks onsite and later characterized for transport and disposal offsite. IDW water manifests are provided in Appendix F.

Water IDW samples were collected in accordance with the IDW Management Plan to characterize the water for transport and disposal offsite. Roux Associates collected three waste characterization water samples from frac tank #1 (CFWC-001-WG, CFWC-002-WG, CFWC-003-WG) from August 2016 through November 2016 following the completion of Round 1 of groundwater and surface water sampling. The sampling results are provided in Appendix F, F1 through F8. Roux Associates provided the sampling results to USEPA and the Oregon Department of Environmental Quality (for notification purposes in the state where the waste will be shipped) on March 24, 2017. USEPA provided their concurrence with the sample results and plan for water disposal via e-mail

on April 4, 2017. The results showed the IDW water (approximately 7,000 gallons of water) was non-hazardous. The results also indicated detections of total cyanide and fluoride in all three samples at concentrations that exceed the USEPA Tapwater RSLs, but are below the USEPA MCLs.

Disposal of water IDW associated with the above referenced samples was completed in May 2017. The first load of water (approximately 5,000 gallons) was transported via tanker truck to Chemical Waste Management, 17629 Cedar Springs Lane, Oregon 97812 on May 11, 2017, followed by the second load of water (approximately 2,000 gallons) on May 16, 2017. Transport of the water was managed by Cascade Drilling.

Roux Associates collected one waste characterization water sample from frac tank #2 (CFWC-004-WG) on June 30, 2017 following the completion of the fourth groundwater sampling event. The sampling results are provided in Appendix F, Tables F1 through F8. Roux Associates provided the sampling results to USEPA and the Oregon Department of Environmental Quality on July 27, 2017. The results showed the IDW water was non-hazardous. The results also indicated detections of total cyanide and fluoride in all three samples at concentrations that exceed the USEPA Tapwater RSLs, but are below the USEPA MCLs. USEPA provided their concurrence with the sample results and plan for water disposal via e-mail on August 2, 2017.

Disposal of water IDW associated with the above referenced sample was completed in August 2017. The water (approximately 3,200 gallons) was extracted from the onsite tank on August 17, 2017, transported via tanker truck, and received by Chemical Waste Management, 17629 Cedar Springs Lane, Oregon 97812 on August 18, 2017 in accordance with the IDW Management Plan. Transport of the water was managed by Cascade Drilling.

The two onsite frac tanks were cleaned by Cascade Drilling on September 7, 2018. The tank contents (2,000 gallons of residual drilling materials and rinsate) were extracted and transported offsite via tanker truck on September 8, 2017 to Chemical Waste Management, 17629 Cedar Springs Lane, Oregon 97812, in accordance with the IDW Management Plan (Roux Associates, 2016b). The two tanks were transported offsite by Cascade Drilling in October 2017.

4.0 GROUNDWATER INVESTIGATION RESULTS

This Section describes the results of the groundwater investigation activities, including groundwater gauging, groundwater sampling, and slug testing.

4.1 Groundwater Elevations/Potentiometric Surfaces and Flow Patterns

Depth to groundwater and potentiometric surface elevations from the four gauging events are provided in Table 2. The elevation data indicates that groundwater elevations (GWE) fluctuate seasonally at varying magnitudes depending on the area of the Site. Near Teakettle Mountain and the landfill area, average water levels fluctuated by approximately 16 feet between March 2017 (low water levels) and June 2017 (high water levels). During the same time period, monitoring wells in the center of the Site and the southern area of the Site fluctuated by 12.5 feet and 17.5 feet, respectively. The table below summarizes average groundwater elevations in three general areas of the Site during each gauging round. The data in the table below further illustrate the points above regarding temporal fluctuations.

Location	Wells Utilized	Average Groundwater Elevation Feet above Mean Sea Level *[ft-amsl])* Round 1 Aug 30, 2016	Average Groundwater Elevation *(ft-amsl)* Round 2 Nov 29, 2016	Average Groundwater Elevation *(ft-amsl)* Round 3 Mar 14/15, 2017	Average Groundwater Elevation *(ft-amsl)* Round 4 June 16, 2017
Teakettle Mountain / Landfill Area	CFMW-002 CFMW-010 CFMW-012 CFMW-014 CFMW-015 CFMW-016 CFMW-019 CFMW-020 CFMW-021	3065.76	3065.87	3063.78	3079.88
Center of the Site (Between Main Plant and Landfills)	CFMW-026 CFMW-027 CFMW-028 CFMW-029 CFMW-031 CFMW-032 CFMW-033 CFMW-034 CFMW-035 CFMW-043 CFMW-044	3063.30	3060.64	3058.27	3071.05

Location	Wells Utilized	Average Groundwater Elevation Feet above Mean Sea Level *[ft-amsl])* Round 1 Aug 30, 2016	Average Groundwater Elevation *(ft-amsl)* Round 2 Nov 29, 2016	Average Groundwater Elevation *(ft-amsl)* Round 3 Mar 14/15, 2017	Average Groundwater Elevation *(ft-amsl)* Round 4 June 16, 2017
Southern Area (Between Main Plant and Flathead River)	CFMW-037 CFMW-038 CFMW-040 CFMW-042 CFMW-045 CFMW-047 CFMW-049 CFMW-050 CFMW-053 CFMW-054	3032.49	3026.59	3023.87	3041.49

The groundwater elevations from monitoring wells screened in the upper hydrogeologic unit were utilized to create groundwater contour maps and to evaluate groundwater flow. The groundwater contour maps are provided in Plates 3 through 6. Overall, groundwater flow across the Site in the upper hydrogeologic unit was generally to the south / southwest direction towards the Flathead River during all four rounds of gauging. The groundwater flow maps also indicate that the hydraulic gradients are consistent across all four rounds and can generally be divided into three distinct areas. Near Teakettle Mountain and in the landfill area of the Site, the groundwater hydraulic gradient is steep and generally mirrors the steeper topography in that portion of the Site. Groundwater elevations in the center of the Site (near the North Percolation Ponds, former Operational Area, and northern half of the Main Plant Area) are consistent over long distances, indicating a relatively flat groundwater hydraulic gradient across the center of the Site (i.e., generally an order of magnitude less than near the landfill area). The gradient then increases in the southern area of the Site between the Main Plant Area and the Flathead River (which is also consistent with the steep drop in topography between the railroad and the river). The table below summarizes the average hydraulic gradients in the three general areas of the Site during each gauging round:

Location	Hydraulic Gradient *(ft/ft)* Round 1 Aug 30, 2016	Hydraulic Gradient *(ft/ft)* Round 2 Nov 29, 2016	Hydraulic Gradient *(ft/ft)* Round 3 Mar 14/15, 2017	Hydraulic Gradient *(ft/ft)* Round 4 June 16, 2017
Teakettle Mountain/ Landfill Area	0.0280	0.0433	0.0536	.0719

Location	Hydraulic Gradient *(ft/ft)* Round 1 Aug 30, 2016	Hydraulic Gradient *(ft/ft)* Round 2 Nov 29, 2016	Hydraulic Gradient *(ft/ft)* Round 3 Mar 14/15, 2017	Hydraulic Gradient *(ft/ft)* Round 4 June 16, 2017
Center of the Site (Between Main Plant and Landfills)	0.0013	0.0028	0.0030	0.0034
Southern Area (Between Main Plant and Flathead River)	0.0131	0.0078	0.0053	0.0199

The groundwater elevations measured during all four sampling events within the deep wells that are screened in the glacial till unit (i.e., below the upper hydrogeologic unit) are also provided on Plates 3 through 6 for comparison with elevations measured in wells screened in the upper hydrogeologic unit. In addition, the table below shows the elevations measured in monitoring well clusters, where there is a well screened within the upper hydrogeologic unit and an adjacent deep well screened below the upper hydrogeologic unit. The table below also includes the elevations measured in monitoring well clusters CFMW-016/CFMW-016a, CFMW-028/CFMW-028a, CFMW-045/CFMW-045a, and CFMW-049/CFMW-049a, which are monitoring well cluster locations where both monitoring wells are screened in the upper hydrogeologic unit.

Monitoring Well Location ID	Geologic Unit	Aug 30, 2016 GWE *(ft-amsl)* Round 1	Nov 29, 2016 GWE *(ft-amsl)* Round 2	March 14/15, 2017 GWE *(ft-amsl)* Round 3	June 16, 2017 GWE *(ft-amsl)* Round 4

CFMW-045a	Upper	3024.38	3022.88	3020.73	3031.33
CFMW-049	Upper	3017.79	3019.44	3018.19	3029.71
CFMW-049a	Upper	3017.69	3019.51	3018.34	3030.05

As shown above, in all cases the elevations measured in deep wells screened below the upper hydrogeologic unit are lower than the elevations in adjacent wells screened within the upper hydrogeologic unit. The differences in elevations between the upper hydrogeologic unit wells and the glacial till wells is typically greater than 25 feet, and in some cases, exceed 50 feet. This large difference is indicative of limited (if any) hydraulic connectivity between the two water bearing zones.

The groundwater elevations measured in monitoring well clusters where both monitoring wells are screened in the upper hydrogeologic unit typically differ by less than 0.2 ft; and often by less than 0.1 ft.

Vertical gradients for each nested well pair for each gauging event and the geometric mean for all events are provided in the table below:

Monitoring Well	Geologic	Aug 30, 2016 Vertical Gradient	Nov 29, 2016 Vertical Gradient	March 14/15, 2017 Vertical Gradient	June 16, 2017 Vertical Gradient	Geometric Mean Vertical Gradient
Location ID	**Unit**	***ft/ft***	***ft/ft***	***ft/ft***	***ft/ft***	***ft/ft***
		Round 1	**Round 2**	**Round 3**	**Round 4**	**All Rounds**
CFMW-003	Upper	0.884	0.879	0.875	0.863	0.875
CFMW-003a	Below Upper					
CFMW-011	Upper	0.534	0.514	0.476	0.547	0.517
CFMW-011a	Below Upper					
CFMW-012	Upper	0.534	0.511	0.477	0.546	0.516
CFMW-012a	Below Upper					
CFMW-019	Upper	0.507	0.482	0.453	0.504	0.486
CFMW-019a	Below Upper					
CFMW-025b	Upper	0.330	0.555	0.524	0.229	0.385
CFMW-025a	Below Upper					
CFMW-032	Upper	0.407	0.385	0.364	0.407	0.390
CFMW-032a	Below Upper					
CFMW-044a	Upper	0.124	0.015	0.101	0.117	0.068
CFMW-044b	Below Upper					
CFMW-053	Upper	0.279	0.161	0.143	0.339	0.216
CFMW-053a	Below Upper					
CFMW-056b	Upper	0.546	0.512	0.497	0.488	0.510
CFMW-056a	Below Upper					
CFMW-016	Upper	0.059	-0.001	0.000	0.003	0.015
CFMW-016a	Upper					
CFMW-028	Upper	-0.002	-0.002	-0.003	-0.003	-0.002
CFMW-028a	Upper					
CFMW-045	Upper	0.087	0.036	0.023	0.123	0.055
CFMW-045a	Upper					
CFMW-049	Upper	0.003	-0.002	-0.004	-0.009	-0.003
CFMW-049a	Upper					

The magnitude of the vertical gradients between the upper hydrogeologic unit and the glacial till vary depending on the location of the well within the Site. The vertical gradients between the two units also show variation temporally, where the lowest gradients were observed during lower water levels (i.e., November 2016 and March 2017).

The vertical gradients calculated for clusters within the upper hydrogeologic unit confirm that there is a limited vertical gradient, and that the direction of the gradient (upward or downward)

may vary temporally at individual well clusters. The only well with a consistently downward gradient was CFMW-045/045a.

4.2 Long Term Elevation Trends from Pressure Transducer Data

Groundwater elevations obtained from pressure transducers were plotted over time to produce hydrographs for the various well locations (Appendix B). Data from April 2016 to late November 2016, which was included in the Phase I Data Summary Report (Roux Associates, 2017a), indicates that the highest Site water levels during this period were observed in late May/early June 2016 and the lowest water levels were observed in late October/early November 2016. The magnitude of groundwater elevation fluctuations was dependent on the location within the Site and the well screen depth. The largest fluctuations were observed in monitoring wells screened in the upper hydrogeologic unit and located near the landfills and Teakettle Mountain, including CFMW-007 (>40 feet) and CFMW-020 (>30 feet). Review of the elevation data compared to precipitation records suggest that the water table elevations may fluctuate significantly over short periods of time (>20 feet over one month) as a result of precipitation events and from contributions of losing streams. Smaller fluctuations were observed in wells located in the northern areas of the Site, including CFMW-001 (approximately 2 feet), and also wells screened below the upper hydrogeologic unit, including CFMW-044b (approximately 8 feet). The fluctuations in these wells are gradual and do not correlate with the short-term precipitation events.

In March 2017, the transducers were moved to their new locations (i.e., nested wells at CFMW-016/16a, CFMW-019/19a, and CFMW-053/53a) as described in Section 3.2. Data from March 2017 through September 2017 were utilized to evaluate groundwater elevation fluctuations in locations around and downgradient of the landfills, and to evaluate differences in groundwater elevation fluctuations in the upper hydrogeologic unit and below the upper the hydrogeologic unit. Note that monitoring wells CFMW-016 and CFMW-016a are both screened in the upper hydrogeologic unit, and therefore were not used to compare differences between the two hydrogeologic units.

The data from monitoring wells CFMW-016 and 019 (both screened in the upper hydrogeologic unit near the Wet Scrubber Sludge Pond) indicate that the highest Site water levels were observed

in late March/early April 2017 and the groundwater elevation levels trended downward through September 2017. Groundwater elevation changes were greater than 20 feet in monitoring well CFMW-019 (located on the southern boundary of the Wet Scrubber Sludge Pond) and groundwater elevation changes were greater than 50 feet in CFMW-016 (located on the eastern boundary of the Wet Scrubber Sludge Pond). Elevation fluctuations of greater than 50 feet were also observed at CFMW-007 (located on the western boundary of the West Landfill) during the same time (data was obtained from the Montana State Bureau of Mines website [MBMG, 2017]). The fluctuations in these upper hydrogeologic unit monitoring wells corresponded with increased seasonal precipitation and snow melt.

Groundwater elevation data from wells screened below the upper hydrogeologic unit did not show large fluctuations like the wells screened in the upper hydrogeologic unit. Monitoring well CFMW-053a and CFMW-019a fluctuated by less than 10 feet between March and September 2017. These fluctuations were gradual and do not correlate with the short-term precipitation events like the wells in the upper hydrogeologic unit. The slower, gradual responses observed in well pairs CFMW-053/053a and CFMW-019/019a further suggests limited connectivity between the deeper unit and the upper hydrogeologic units proximal to these well pairs. In addition, cyanide, present at concentrations between 791 and 1,770 µg/L in upper unit well CFMW-019 and 238 and 386 µg/l in upper unit well CFMW-053, was non-detect in monitoring wells CFMW-019a and CFMW-053a (screened below the upper hydrogeologic unit) in all four Phase I sampling rounds. These results further support that there is limited connectivity, if any, between the deeper unit and the upper hydrogeologic units proximal to these well pairs.

Pressure transducers will continue to be utilized long term at the Site to evaluate seasonal groundwater elevations. Data will be downloaded during future monitoring well gauging events.

4.3 Groundwater Quality

The following sections provide a summary of groundwater quality based on field and laboratory analytical data that were generated during the four rounds of data collection. Tables containing all of the groundwater quality data generated during the work are provided in Appendix G, Tables 1 through 4. Additionally, laboratory data reports were provided to the USEPA as separate

submittals throughout the work. Electronic Data Deliverables (EDDs) with the groundwater data were also provided online for download by the USEPA from the CFAC RI/FS project database.

4.3.1 Field Parameters

Field parameters measured during well purging activities immediately prior to collection of groundwater samples are provided on field datasheets included in Appendix C and are summarized on Table 5. The field parameter data were reviewed to evaluate any potential anomalies in general groundwater chemistry that could potentially be influencing the groundwater sampling results. Field parameters were observed to fluctuate depending on the round of sampling. However, except for elevated pH, no anomalies were noted in the field parameters that are expected to influence groundwater sampling results. The pH measurement data is further discussed in Section 4.3.1.1 and 6.2.

4.3.1.1 Monitoring Well pH

As part of the field parameter data review during monitoring well development and sampling, anomalously high pH (i.e., above 10 Standard Units [SUs]) was identified in 11 monitoring wells (one well installed in the upper hydrogeologic unit and ten wells installed deeper). These monitoring wells also typically produced elevated conductivities and low ORP. Based on the distribution of wells across the Site and the groundwater chemistry observed in the sampling data (as discussed in Section 6.2) the elevated pH conditions were attributed to the cement grout used during well construction. The elevated pH conditions were discussed with the USEPA and MDEQ during project update conference calls and via email correspondence. The USEPA requested that the pH conditions continue to be assessed as part of the ongoing groundwater monitoring activities at the Site.

As part of the pH evaluation, Roux Associates mobilized personnel from Hydrometrics to the Site on October 11, 2016 with the objective of determining if further purging groundwater from the wells (i.e., flushing the well screen) could result in a reduction of pH. Hydrometrics personnel were onsite from October 11 through 14, 2016 and October 18 through 20, 2016 and purged all 11 wells that were identified as having pH over 10. During the purging, Hydrometrics monitored the pH conditions to observe whether pH was reduced in each well. The monitoring indicated that pH in six of the 11 wells were reduced to below 10 as a result of the purging activities.

Monitoring wells with pH remaining above 10 after the purging included CFMW-008a, 032a, 044a, 53a, and 57a.

After the purging efforts performed by Hydrometrics were completed, Cascade subsequently mobilized to the Site on December 12 through 15, 2016 to complete additional purging at the eleven monitoring wells. During the purging, Cascade monitored the pH conditions to observe whether pH was reduced in each well. The monitoring indicated that six of the 11 wells had pH over 10; monitoring wells CFMW-008a, 032a, 044a, 049a, 53a, and 57a.

The groundwater pH measured during all four groundwater sampling events are provided in the table below for those wells which were initially identified as exhibiting elevated pH. The following measurements were identified as the stabilized pH readings upon completion of purging at each well prior to sampling during each of the four rounds. These measurements were taken using a Horiba U-52 water quality meter.

Monitoring Well Location ID	Geologic Unit	Aug 30, 2016 pH Round 1	Nov 29, 2016 pH Round 2	Mar 14/15, 2017 pH Round 3	June 16, 2017 pH Round 4
CFMW-008a	Upper	9.10	8.58	8.94	12.59
CFMW-011a	Below Upper	10.18	7.67	7.97	7.46
CFMW-016a	Upper	11.39	8.84	7.34	11.53
CFMW-019a	Below Upper	10.24	8.38	8.62	7.96
CFMW-032a	Below Upper	14.00	12.74	13.11	12.63
CFMW-044a	Upper	12.25	9.10	9.18	8.50
CFMW-047	Upper	10.86	7.81	7.44	7.91
CFMW-049a	Upper	12.46	10.49	12.84	12.08
CFMW-053a	Below Upper	14.00	12.46	13.22	10.53
CFMW-057a	Below Upper	12.80	12.91	12.24	12.57
CFMW-059a	Below Upper	14.00	8.86	9.32	9.38

The pH in groundwater was further evaluated based on the geochemical data collected during sampling and is described in Section 6.2.

4.3.2 Overview of Groundwater Quality based on Laboratory Analytical Results

Laboratory analytical results for groundwater samples collected from Site monitoring wells were evaluated to determine the presence, or lack thereof, of COPCs in Site groundwater and to evaluate seasonal changes in concentrations. Tables 6 through 15 provide a statistical summary of the analytical results for groundwater data from monitoring wells screened in the upper hydrogeologic unit and below the upper hydrogeologic unit, respectively, during each round of sampling. These tables identify the frequency of detection; as well as the minimum, maximum and average detected concentrations, of each analyte in groundwater for the respective set of monitoring wells. Where concentrations were non-detect, the statistics were calculated using ½ the MDL. The MDLs achieved throughout the Phase I Site Characterization, relative to USEPA screening levels, were evaluated and further described in Section 7.2. In addition, the statistical summary tables provide the frequency that the measured concentration of each analyte in groundwater exceeded the following human health screening criteria as noted in the RI/FS Work Plan (Roux Associates, 2015a) and Phase I SAP (Roux Associates, 2015b):

- MDEQ Circular DEQ-7, Human Health Numeric Water Quality Standards (MDEQ, 2012);
- USEPA Drinking Water Maximum Contaminant Levels (MCLs) (USEPA, 2016a); and
- USEPA Tapwater Regional Screening Levels (RSLs) (USEPA, 2016b).

The groundwater at the Site is not used as drinking water, however, all comparisons of analytical results to screening criteria, including drinking water and tapwater criteria, are provided to enable better understanding of the relative concentrations of the various analytes. The screening criteria are developed by the USEPA using conservative assumptions and are not action levels to which COPCs must be remediated. For example, the USEPA Tapwater RSLs are so low, that for many analytes, any detection results in an exceedance. The presence of analytes in groundwater at concentrations exceeding USEPA Tapwater RSLs does not indicate that a risk exists or that remedial action is required, but rather, that further evaluation of that particular analyte and exposure scenario is warranted during the risk assessment phase of the RI/FS, where the risk to human health and ecosystems, as applicable, will be assessed. Remedial actions will be based on such assessed risks and not screening criteria.

In addition to comparisons to the human health screening criteria, the statistical summary tables provide the frequency that the measured concentration of each analyte in groundwater exceeded the concentration measured in monitoring well CFMW-001, which was identified in the RI/FS Work Plan (Roux Associates, 2015a) as a background monitoring well based upon its location in the northern area of the Site, upgradient of potential source areas.

The following sections provide an evaluation of groundwater results from all four sampling rounds.

4.3.2.1 Cyanide in Groundwater

The statistical summary of cyanide in groundwater in Rounds 1 through 4 are shown in Tables 6 through 15. Thematic dot maps showing the concentrations of cyanide in groundwater in Rounds 1 through 4 are provided in Appendix H, Plates 1 through 4. Iso-concentrations maps of cyanide concentrations in groundwater in Rounds 1 through 4 are shown on Plate 7. Maps presenting a comparison of total concentrations of cyanide and free cyanide in Rounds 3 and 4 are provided on Plates 8 and 9, respectively. Table 16 presents a comparison of concentrations of total and dissolved cyanide and free cyanide collected during Round 4. These data indicate the following:

- Total cyanide was detected in approximately 84% of the groundwater samples collected from monitoring wells screened in the upper hydrogeologic unit and 13% of the groundwater samples collected from wells screened below the upper hydrogeologic unit throughout all four rounds of sampling. Total cyanide was detected in 91%, 80%, 85%, and 78% of the groundwater samples collected from wells screened in the upper hydrogeologic unit during Rounds 1 through 4, respectively. Total cyanide was detected in 15%, 15%, 15%, and 8% of the groundwater samples collected from wells screened below the upper hydrogeologic unit during Rounds 1 through 4, respectively.

- In each location where cyanide was detected, it exceeded the USEPA Tapwater RSL of 0.15 µg/L. Total cyanide was detected at concentrations greater than the DEQ-7 Human Health Standard / USEPA MCL of 200 µg/L in groundwater from monitoring wells screened in the upper hydrogeologic unit in 21 samples during Round 1 (35% of samples), 18 samples during Round 2 (31% of samples), 21 samples during Round 3 (34% of samples), and 18 samples during Round 4 (29% of samples).

- Total cyanide did not exceed the DEQ-7 Human Health Standard / USEPA MCL of 200 µg/L in any groundwater samples from monitoring wells screened below the upper hydrogeologic unit in all four rounds of sampling. The maximum concentration of total cyanide detected in groundwater below the upper hydrogeologic unit was 10.5 µg/L during Round 4.

- The highest concentrations of total cyanide were located downgradient of the West Landfill and Wet Scrubber sludge pond during all four rounds of sampling. The highest detection of total cyanide was observed in monitoring well CFMW-015 (located on the western boundary of the Wet Scrubber Sludge Pond and downgradient of the West Landfill) in June 2017 (Round 4) at a concentration of 8,120 µg/L. Groundwater from monitoring well CFMW-017, screened beneath the Central Landfill, was not sampled during Rounds 1 and 2 due to insufficient volume of water in the well. The groundwater from monitoring well CFMW-017 was sampled during Round 3 and 4, and during Round 3 the detected total cyanide concentration of 1,880 µg/L exceeded the DEQ-7 Human Health Standard / USEPA MCL.

- A consistent pattern was observed during all four rounds of sampling; cyanide migrates in south / southwesterly direction from the aforementioned landfills toward the Flathead River. Total cyanide concentrations in groundwater within the upper hydrogeologic unit decrease with increasing distance away from the landfills.

- Variable concentrations of total cyanide were observed downgradient of the West Landfill / Wet Scrubber Sludge Pond, in the area located around the North-East Percolation Pond and to the west of the Main Plant buildings. Immediately south and southwest of the NE Percolation Pond, an area of lower cyanide concentrations is typically observed. The size of the lower concentration area varies from round to round, but appears largest (as delineated by the closed 300 µg/l contour) in the June 2017 sampling event. The contour maps for all four rounds indicate no increase in concentrations in monitoring wells located downgradient of the Main Plant.

- Total cyanide was not observed to migrating toward Aluminum City, and total cyanide was non-detect in monitoring wells next to Aluminum City in all four rounds of sampling.

- Free cyanide was detected in 56% and 68% of the upper hydrogeologic unit samples analyzed for free cyanide during Rounds 3 and 4, respectively. In each location where free cyanide was detected, it exceeded the USEPA Tapwater RSL of 0.15 µg/L. Free cyanide was only detected at concentrations greater than the DEQ-7 Human Health Standard / USEPA MCL of 200 µg/L at one location during Round 3 (CFMW-002) at a concentration of 306 µg/L. Free cyanide did not exceed the DEQ-7 Human Health Standard / USEPA MCL of 200 µg/L at any locations during Round 4. Detections of free cyanide were generally concentrated near the West Landfill, Wet Scrubber Sludge Pond, Former Drum Storage Area, and Main Plant Area. Detected concentrations of free cyanide were less than detected concentrations of total cyanide at all locations. Free-cyanide was not detected in any groundwater samples from monitoring wells screened below the upper hydrogeologic unit.

- Concentrations of total and dissolved cyanide and free cyanide were similar, with the total concentrations in most instances being slightly higher than dissolved.

- Total cyanide was detected in background monitoring well CFMW-001 at a concentration of 2.4 µg/L in Round 1, and was non-detect in Rounds 2 through 4.

4.3.2.2 Fluoride in Groundwater

The statistical summary of fluoride in groundwater in Rounds 1 through 4 are shown in Tables 6 through 15. Thematic dot maps showing the concentrations of fluoride in groundwater in Rounds 1 through 4 are provided in Appendix H, Plates 5 through 6. Iso-concentrations maps of fluoride concentrations in groundwater in Rounds 1 through 4 are shown on Plate 10. Table 16 presents a comparison of concentrations of total and dissolved fluoride collected during Round 4. These data indicate the following:

- Fluoride was detected in more than 97% of the samples during each groundwater sampling round. Fluoride was detected at concentrations exceeding the USEPA Tapwater RSL of 80 µg/L in 97% of groundwater samples from monitoring wells screened in the upper hydrogeologic unit and 90% of groundwater samples from monitoring wells screened below the upper hydrogeologic unit.

- Fluoride was detected at concentrations greater than the DEQ-7 Human Health Standard / USEPA MCL of 4,000 µg/L from monitoring wells screened in the upper hydrogeologic unit in 15 % (seven) of samples during Round 1, 9% (four) of samples during Round 2, 17% (eight) of samples during Round 3, and 16% (eight) of samples during Round 4. Fluoride did not exceed the DEQ-7 Human Health Standard / USEPA MCL in any groundwater samples from monitoring wells screened below the upper hydrogeologic unit in all four rounds of sampling. Fluoride concentrations in monitoring wells screened below the upper hydrogeologic unit were typically an order of magnitude less than concentrations of fluoride in upper hydrogeologic unit monitoring wells. Review of Table 16 shows that total and dissolved concentrations of fluoride were similar.

- Similar to cyanide, the highest concentrations of fluoride were primarily located downgradient of the West Landfill and Wet Scrubber sludge pond during all four rounds of sampling. The highest detection of fluoride was observed in monitoring well CFMW-015 (located on the western boundary of the Wet Scrubber Sludge Pond and downgradient of the West Landfill) in June 2017 (Round 4) at a concentration of 55,300 µg/L (dissolved concentration).

- Fluoride was detected in background monitoring well CFMW-001 at concentrations of 91.7 µg/L, 132 µg/L, 184 µg/L, and 120 µg/L; in Rounds 1 through 4, respectively. These concentrations are similar to concentrations measured in public and community water supply wells as noted in the bullet above.

4.3.2.3 Metals in Groundwater

The statistical summary of metals in groundwater in Rounds 1 through 4 are shown in Tables 6 through 15. Thematic dot maps showing the concentrations of select metals in groundwater in Rounds 1 through 4 are provided in Appendix H, Plates 7 through 44. Table 16 presents a comparison of concentrations of total and dissolved metals exceeding the DEQ-7 Human Health

Standard / USEPA MCL screening levels collected during Round 4. These data indicate the following:

- Many metals occur naturally in the groundwater at the Site, and thus metals are expected to be detected frequently in groundwater samples. The most commonly detected metals in groundwater in all four sampling rounds were barium, calcium, magnesium, potassium, and sodium. These metals were detected in 100% of groundwater samples collected during all four rounds of groundwater sampling.

- Aluminum, antimony, arsenic, barium, chromium, cobalt, iron, manganese, selenium, vanadium, and zinc were detected at concentrations greater than USEPA Tapwater RSLs.

- Arsenic, antimony, barium, and zinc were the only metals detected in groundwater samples at concentrations exceeding their respective DEQ-7 Human Health Standard and/or USEPA MCL. The exceedances were limited to one sampling location for each metal in each sampling round; with the exception of arsenic which exceeded the USEPA MCL at a maximum of four locations during Round 4.

- Although concentrations of detected metals are generally below the DEQ-7 Human Health Standards / USEPA MCLs, the concentrations of select metals including aluminum, arsenic, cobalt, iron, and lead are highest in the same monitoring wells as the elevated fluoride and cyanide located immediately downgradient of the West Landfill and Wet Scrubber Sludge Pond.

- Several of the deep wells have notably higher calcium concentrations (e.g., maximum of 922,000 µg/L [dissolved concentration] at CFMW-053a during Round 1), as compared to concentrations of calcium within the wells screened in the upper hydrogeologic unit (average concentration of 59,476 µg/L). These elevated calcium concentrations in the deep wells appear to be attributable to the cement grout used during the well construction as noted in Section 6.2.

- During Round 4, metals and cyanide analyses included total and dissolved (i.e., filtered). Table 16 provides a comparison of total and dissolved results for metals that exceeded their respective DEQ-7 Human Health Standard and/or USEPA MCL during the fourth-round of groundwater sampling. These data show that total and dissolved concentrations were similar, with the total concentrations in most instances being slightly higher than dissolved. In 15 of 20 samples where total zinc was detected, dissolved zinc was below detection limits.

- Metal analytes that exceeded their respective DEQ-7 Human Health Standard and/or USEPA MCL during the groundwater sampling, including arsenic, barium, and zinc, were also compared to concentrations measured in background monitoring well CFMW-001. The results of this comparison are provided in Tables 7 through 10, and 12 through 15.

4.3.2.4 VOCs and SVOCs in Groundwater

The statistical summary of VOCs and SVOCs in groundwater in Rounds 1 through 4 are shown in Tables 6 through 15. These data indicate the following:

- VOCs and SVOCs were detected in less than 10% and 4% respectively, of all groundwater samples collected from monitoring wells screened in the upper hydrogeologic unit throughout the sampling. VOC and SVOC detections did not exceed DEQ-7 Human Health Standards / USEPA MCLs in any groundwater samples.

- Polycyclic Aromatic Hydrocarbons (PAHs), a subset of the SVOCs found most frequently in soil during the Phase I Site Characterization, were not detected in any groundwater samples collected during the four rounds of sampling.

- The RI/FS Work Plan (Roux Associates, 2015a) also specified the Vapor Intrusion Screening Level (VISL) calculator as a criterion to be considered at the Site. The maximum concentrations of each VOC detected in groundwater within the upper hydrogeologic unit were entered into the USEPA VISL Groundwater Concentration to Indoor Air Concentration (GWC-IAC) Calculator Version 3.5.1 (USEPA, 2016c), as presented in Appendix I. The results from Round 1 provided in the Phase I Data Summary Report (Roux Associates, 2017a) indicate that all estimated vapor intrusion carcinogenic risks were less than $1.0x10^{-6}$, and that only trichloroethene (TCE), based upon a detected value of 0.76 µg/L at one location, was above the hazard quotient (HQ) of 0.1. It is noted that the groundwater average temperature used in this evaluation was 25°C. A review of the field datasheets for all four rounds of sampling (Appendix C) indicates that the average groundwater temperature is less than 11°C. Based on a Site-specific groundwater temperature, the results indicate that all estimated vapor intrusion carcinogenic risks were less than $1.0x10^{-6}$ in all four rounds; and all estimated HQs were less than 0.1

4.3.2.5 General Chemistry in Groundwater

General chemistry analyses including alkalinity, ammonia, chloride, hardness (as calcium carbonate), nitrate + nitrite (as nitrogen), orthophosphate (as phosphorus), and sulfate were performed on groundwater samples to obtain data that could be utilized in chemical fate and transport evaluations and modeling, if needed, in the future as part of the RI/FS. General chemistry results were also compared to the standards and RSLs where available. The statistical summary of general chemistry results for groundwater in Rounds 1 through 4 are shown in Tables 6 through 15. Thematic dot maps showing the concentrations of general chemistry results in groundwater in Rounds 1 through 4 are provided in Appendix H, Plates 45 through 58. These data indicate the following:

- Nitrate + nitrite (as nitrogen) is the only general chemistry parameter with a DEQ-7 Human Health Standard / USEPA MCL (i.e., 10,000 µg/L). Nitrate + nitrite (as nitrogen) was detected at frequencies ranging from 66% to 83% (between the upper hydrogeologic

unit and below upper hydrogeologic unit) during the four sampling rounds. A maximum number of exceedances of the USEPA MCL occurred during Round 3, when seven samples exceeded the criteria. The exceedances of nitrate + nitrite (as nitrogen) USEPA MCL during all four rounds of sampling were primarily in monitoring wells located immediately downgradient of the West Landfill / Wet Scrubber Sludge Pond, in the same area as the elevated cyanide and fluoride concentrations.

- Review of the thematic maps in Appendix H also indicates that sulfate and ammonia concentrations are typically highest downgradient of the landfills.

4.4 Seasonal Variability of Concentrations in Groundwater Samples

Concentrations of total cyanide and fluoride from the four groundwater sampling rounds were tabulated for comparison with groundwater elevations to evaluate if COPC concentrations varied seasonally. For each monitoring well, the minimum and maximum detected concentrations of total cyanide and fluoride were identified with their associated sampling round. Additionally, the minimum and maximum groundwater elevations for each monitoring well were identified. The comparison table is provided as Table 17.

As described in Section 4.1 and shown in Table 17, the maximum groundwater elevation in each well occurred during Round 4 (June 2017) with only one exception. Round 4 was also when the greatest number of wells (but less than 50 percent of the wells) exhibited the minimum concentrations of total cyanide and fluoride.

In general, cyanide and fluoride were detected in the same monitoring well locations during each round of sampling and the primary source areas of cyanide and fluoride (i.e., the West Landfill, Wet Scrubber Sludge Pond, and Center Landfill) do not appear to change temporally. Iso-concentrations maps provided in Plates 7 and 10 indicate that the overall shape of the spatial distribution of total cyanide and fluoride detections were similar across the four rounds and appears to mimic the groundwater flow directions from the primary source areas towards the Flathead River. The iso-concentration contours on Plates 7 and 10 also indicate that the concentrations within the contoured area may vary seasonally, primarily in the areas immediately north and west of the Main Plant building.

4.5 Slug Testing Results

Data collected during pneumatic and mechanical slug testing activities were recorded utilizing down-hole pressure transducers manufactured by In-Situ. For the pneumatic slug testing, change in head (i.e., change in groundwater elevation in the monitoring well) was recorded every 0.1 second (s). For the mechanical slug tests, change in head was recorded every 0.25 second. Slug testing data was plotted as normalized head in feet (measured displacement divided by the initial displacement) over time in seconds for each test performed and the data plots are provided as Appendix J. The data from each slug test were evaluated in accordance with the procedures outlined in the SOP titled "Standard Operating Procedure 4.10 for Analyzing Slug Test Data." An analytical solution was selected for each set of data and was utilized to determine hydraulic conductivity values for each slug test. The data solutions were computed using a combination of Aqtesolv Analysis Software (HydroSOLVE, 2007) and Geoprobe Slug Test Analysis Software (Geoprobe, 2005). The Geoprobe software has less manual curve matching functionality that Aqtesolv. Therefore, for monitoring wells exhibiting very slow recovering data, the curve matching functionality in Aqtesolv was utilized.

4.5.1 Slug Test Analysis Methods, Inputs, and Assumptions

Table 18 summarizes the methods, inputs and assumptions that were utilized to perform the slug test data analysis. The required input data for well construction details and aquifer characteristics were obtained from monitoring well construction logs, which are included in Appendix K. Based on the hydrogeologic conceptual model for the Site and the monitoring well logs, all 43 monitoring wells where slug testing was performed were classified as unconfined and partially penetrating wells. The aquifer thickness at each location was estimated by calculating the difference in the depth to till and depth to water for wells screened in the upper hydrogeologic unit; and calculating the difference in the estimated depth to bedrock and depth to water for wells screened below the upper hydrogeologic unit.

The primary method selected for analysis of the slug testing data was the Bouwer & Rice (1976) solution (Butler, 1997), which is applicable for homogeneous, isotropic, unconfined conditions, with partially penetrating wells and overdamped well response. The Bouwer-Rice equation used to calculate hydraulic conductivity is:

$$K = \frac{R_C^2 \ln\left(\frac{R_e}{R_s}\right)}{2L_e T_{0.37}}$$

Where:

K = hydraulic conductivity
R_c = radius of the well casing
R_e = effective radius of boring, empirical parameter
R_s = effective radius of the screen
L_e = effective length of the screen
$T_{0.37}$ = time it takes water level to rise or fall 37% of initial change

During analysis of the data utilizing the Bouwer Rice method, a straight-line plot of the ratio h/h_0 on log scale versus time is automatically fitted to the measured data in Aqtesolv (HydroSOLVE, 2007) or the Geoprobe Slug Test Analysis software (Geoprobe, 2005). Manual curve fitting was completed in overdamped cases where adjustments to the automatic curve matching were deemed necessary.

For wells that demonstrated an oscillatory (i.e., underdamped) response, the Springer and Gelhar, 1991 solution was utilized to evaluate the data. This solution accounts for inertial effects in the well and oscillatory slug test response in high-hydraulic conductivity aquifers by introducing a dimensionless dampening factor (C_d) to the Bouwer & Rice solution. The Springer and Gelhar equation used to calculate hydraulic conductivity is:

$$K = \left(\frac{t_d}{t}\right)\left(\frac{R_C^2 \ln\left(\frac{R_e}{R_s}\right)}{2L_e C_d}\right)$$

Where:

K = hydraulic conductivity
t_d = dimensionless time parameter
t = measured time
R_c = radius of the well casing
R_e = effective radius of boring, empirical parameter

R_s = effective radius of the screen
L_e = effective length of the screen
C_d = dampening parameter

4.5.2 Slug Test Analysis Results

Results of the slug testing analysis are summarized on Table 18 for the tests conducted at each monitoring well. As described in Section 3.7, two tests were generally completed at each location; therefore Table 18 also provides the geometric mean hydraulic conductivity based upon the multiple tests conducted at each well.

As described in Section 3.7, in general, each one-foot displacement and two-foot displacement test was conducted a second time to assess the reproducibility of the data and the hydraulic conductivity values. For each displacement interval, the relative percent difference (RPD) was calculated utilizing the hydraulic conductivity values from the initial displacement test and reproduced test. The RPD calculated for wells screened within the upper hydrogeologic unit ranged from 0% to a maximum of 52% RPD, with the maximum RPD occurring in the 1-foot displacement test at monitoring well CFMW-037. The median RPD calculated for wells screened in the upper hydrogeologic unit is 6%. The RPD calculated for wells screened below the upper hydrogeologic unit ranged from 0% to a maximum of 186% RPD, with the maximum RPD occurring in the 2-foot displacement test at monitoring well CFMW-057a. The median RPD calculated for wells screened below the upper hydrogeologic unit is 7.5%.

The table below provides a summary of the minimum, maximum, and geometric mean hydraulic conductivity values from slug tests of wells screened in the upper hydrogeologic unit and the wells screened below the upper hydrogeologic unit. The results suggest that the geometric mean hydraulic conductivity of the upper hydrogeologic unit is higher than the geometric mean hydraulic conductivity of the materials beneath the upper hydrogeologic unit. These hydraulic conductivity values appear to be consistent with geologic observations recorded in boring logs during drilling, which generally indicate wells below the upper hydrogeologic unit are screened in finer grained materials. Additionally, the wide range of estimated hydraulic conductivity values is indicative of the heterogeneous geological conditions that are encountered beneath the Site.

The geometric mean in the table below are reflective of geometric means from all displacement intervals at the respective upper hydrogeologic unit and below upper hydrogeologic unit monitoring well locations.

Hydrogeologic Unit	**Minimum Estimated Hydraulic Conductivity** ***(ft/day)***	**Maximum Estimated Hydraulic Conductivity** ***(ft/day)***	**Median Estimated Hydraulic Conductivity** ***(ft/day)***	**Geometric Mean Estimated Hydraulic Conductivity** ***(ft/day)***
Upper Hydrogeologic Unit	0.11	327.01	15.01	11.1
Below Upper Hydrogeologic Unit	0.004	113.60	0.05	0.27

5.0 SURFACE WATER MONITORING AND QUALITY RESULTS

This Section describes the results of the surface water investigation activities, including surface water discharge monitoring and surface water sampling.

5.1 Surface Water Discharge Monitoring

Discharge of Cedar Creek and Cedar Creek Drainage Overflow Ditch were measured utilizing a mechanical current-meter method as described in Section 3.6. Discharge was measured at the same locations where surface water samples were collected, as shown on Plate 2. Results of the discharge calculations are summarized in the table below. It should be noted that water was not observed to be present in the Cedar Creek Drainage Overflow Ditch throughout most of the field program. Discharge in the overflow ditch was measured on June 7, 2016 when water was observed to be present and surface water sampling was also conducted in tandem (pre-Round 1) as described in Section 3.4.1.

Location ID	Feature	June 7, 2016 Discharge (ft^3/s) Pre-Round 1	Aug 29/30, 2016 Discharge *(ft^3/s)* Round 1	Nov 30, 2016 Discharge *(ft^3/s)* Round 2	April 4, 2017 Discharge *(ft^3/s)* Round 3	June 12/13, 2017 Discharge *(ft^3/s)* Round 4
CFSWP-009	Cedar Creek Drainage Overflow Ditch	2.45	Dry	Dry	20.65	0.17
CFSWP-010	Cedar Creek Drainage Overflow Ditch	11.26	Dry	Dry	36.72	5.87
CFSWP-011	Cedar Creek Drainage Overflow Ditch	15.09	Dry	Dry	45.41	5.16
CFSWP-012	Cedar Creek Drainage Overflow Ditch	13.97	Dry	Dry	42.34	8.74
CFSWP-013	Cedar Creek Drainage Overflow Ditch	16.88	Dry	Dry	54.98	13.07
CFSWP-014	Cedar Creek	NM	7.09	12.01	10.87	19.94
CFSWP-015	Cedar Creek	NM	4.52	17.72	14.90	14.41

Location ID	Feature	June 7, 2016 Discharge (ft^3/s) Pre-Round 1	Aug 29/30, 2016 Discharge *(ft^3/s)* Round 1	Nov 30, 2016 Discharge *(ft^3/s)* Round 2	April 4, 2017 Discharge *(ft^3/s)* Round 3	June 12/13, 2017 Discharge *(ft^3/s)* Round 4
CFSWP-016	Cedar Creek	NM	5.87	17.06	11.87	17.89
CFSWP-025	Cedar Creek	NM	NM	NM	7.42	14.88

The discharge was evaluated at multiple points along the surface water bodies in an effort to confirm the preliminary conceptual site model, that both Cedar Creek and Cedar Creek Drainage Overflow are acting as losing streams as they flow through the Site. In the Cedar Creek Drainage Overflow Ditch, the discharge measured at locations on the north end of the Site were typically higher than the locations at the south parts of the Site. These data indicate that the ditch was acting as a losing stream throughout the entire year (when wet) and thus losing water infiltration into the groundwater system. These data are also supported by visual field observations throughout the program where the north end of the Cedar Creek Drainage Overflow Ditch was observed to be wet, while the south end of the ditch was dry at the same time.

In Cedar Creek, the stream discharge did not decrease consistently from upstream to downstream measurement locations. The increases could be attributed to local surface water inputs from the west and/or be within the margin of error of the field measurement method. As documented within the Phase I Data Summary Report (Roux Associates, 2017a), the creek bed of Cedar Creek is located above the water table in the upper hydrogeologic unit; indicating that it is not a groundwater discharge location.

Due to the size and flow of the Flathead River, discharge measurements could not be collected utilizing the mechanical flow meter method. As part of the Phase I Site Characterization, data was reviewed from the nearest USGS gauging station (Station No. 12363000) located approximately three miles downstream of the Site to understand the general conditions of the Flathead River between April 2016 and June 2017.

Appendix A presents two graphs depicting the discharge of the Flathead River over various periods of time. Appendix A1 shows the average annual daily discharge over the period of record

from 1952 to 2017. During this time, the peak average annual daily discharge for years 1952 through 2017 occurred in 1974, with an average annual daily discharge of 14,440 cubic feet per second (cfs). The lowest average annual daily discharge occurred in 2001, with a minimum average annual daily discharge of 5,261 cfs. This graph depicts a consistent pattern of discharge fluctuation occurs each year. During the Phase I Site Characterization, the average annual daily discharges for 2016 and 2017 were 8,850 cfs and 12,622 cfs, respectively (2017 average annual daily discharge is based on 2017 average through October 31, 2017).

Appendix A2 provides a more detailed look at the discharge and river elevation for 2016 and 2017. The data indicates that average daily discharge of the Flathead River during the four rounds of sampling (April 2016 through June 2017) peaked on May 13, 2017, with a value of 45,800 cubic feet per second (cfs); which was greater than the peak average daily discharge recorded in 2016 (i.e., 28,900 cfs on April 24, 2016). The lowest observed average daily discharge during all four rounds was 3,540 cfs on February 3, 2017. During the gauging events on August 30, 2016, November 29, 2016, March 14/15, 2017, and June 16, 2017, the daily mean discharge was 3,800 cfs, 7,970 cfs, 8,110 cfs, and 25,400 respectively.

A temporary staff gauge was also installed within the Flathead River to enable measurement of river level conditions immediately adjacent to the Site. The temporary staff gauge was surveyed as part of monitoring well surveying activities to allow for use of measured surface water elevations when evaluating groundwater flow directions, and potential groundwater / surface water interaction. Surface water elevations from the staff gauge provided in Table 2 are included in the table below:

Flathead River Surface Water Elevation measured on Staff Gauge *(ft-amsl)*

Round 1 August 30, 2016	Round 2 November 29, 2016	Round 3 March 14/15, 2017	Round 4 June 16, 2017
3014.24	3015.77	3015.67	3019.08

The data from the staff gauge indicate that water levels of the Flathead River next to the Site were highest during the fourth round of sampling in June 2017 and that the Flathead River elevations fluctuated by at least 4.5 feet over four rounds of measurements. Note that these single date

elevation measurements did not capture the absolute low and high-water levels as recorded by the USGS gauging station at Columbia Falls where an approximate 10 ft fluctuation in Flathead River water levels was observed.

5.2 Surface Water Quality

The following section provides a summary of surface water quality based on laboratory analytical data and field data that were generated during the four rounds of sampling. Data tables with surface water data generated during the work are provided in Appendix L. Additionally, laboratory data reports were provided to the USEPA as separate submittals throughout the work. EDDs with the surface water data were provided online for download by the USEPA from the CFAC RI/FS project database.

5.2.1 Field Parameters

Field parameters measured during surface water sampling activities are provided on field datasheets included in Appendix C and are summarized on Table 19. The field parameter data were reviewed to evaluate any potential anomalies in general surface water chemistry that could potentially be influencing the surface water sampling results. No anomalies were noted and the field parameters measured appear to be consistent with values expected to occur in the natural environment.

5.3 Overview of Surface Water Quality from Laboratory Data

Laboratory analytical data for the surface water samples collected from Site were evaluated to determine the presence, or lack thereof, of COPCs in Site surface water. Tables 20 through 29 provides a statistical summary of the analytical results for each round of sampling. These tables identify the frequency of detection; as well as the minimum, maximum and average detected concentrations, of each analyte in surface water. Where concentrations were non-detect, the statistics were calculated using ½ the method detection limit.

The statistical summary tables (Tables 20 through 24) provide the frequency that the measured concentration of each analyte in surface water exceeded the following human health screening criteria as noted in the RI/FS Work Plan (Roux Associates, 2015a), Phase I SAP (Roux

Associates, 2015b), Phase I SAP Addendum (Roux Associates, 2016a), and Screening Level Ecological Risk Assessment (SLERA) (Roux Associates, 2017b):

- MDEQ Circular DEQ-7, Human Health Numeric Water Quality Standards (MDEQ, 2012);
- USEPA Drinking Water Maximum Contaminant Levels (USEPA, 2016a); and
- USEPA Tapwater RSLs (USEPA, 2016b).

Like groundwater, surface water at the Site is also not used as drinking water. However, all comparisons of analytical results to screening criteria, including drinking water and tapwater criteria, are provided to enable better understanding of relative concentrations of various analytes and not for purposes of assessing remedial alternatives.

The statistical summary tables (Tables 25 through 29) also provide the frequency that the measured concentration of each analyte in surface water exceeded the minimum ecological screening value (ESV) for the ecological screening criteria as noted in the RI/FS Work Plan (Roux Associates, 2015a), Phase I SAP (Roux Associates, 2015b), Phase I SAP Addendum (Roux Associates, 2016a), and SLERA (Roux Associates, 2017b):

- MDEQ Circular DEQ-7 Acute Aquatic Life Standards (MDEQ, 2012);
- MDEQ Circular DEQ-7 Chronic Aquatic Life Standards (MDEQ, 2012);
- USEPA National Recommended Water Quality Criteria (USEPA, 2004);
- Toxicological Benchmarks for Screening Potential Contaminants of Concern for Effects on Aquatic Biota: (Suter and Tsao, 1996);
- Suter & Tsao, 1996. GLWQI Tier II SAV/SCVs and ORNL LCVs provided in Table 1 and ORNL Population EC20s provided in Table 2;
- USEPA Region 3 Freshwater Screening Benchmark (USEPA, 2006); and
- Canadian Water Quality Guidelines, Summary Table (CCME, 2008).

Based on the statistical summary and a review of the surface water conditions, thematic dot maps displaying data for cyanide, fluoride, and selected metals were created to visually evaluate the areal distribution and magnitude of exceedances of each compound and are provided in Appendix M. The sections below provide additional detail regarding the analytical results for the

surface water samples during each round of sampling. The following sections provide an evaluation of surface water results from all four sampling rounds.

5.3.1 Cyanide in Surface Water

The statistical summary of cyanide in surface water in Rounds 1 through 4 are shown in Tables 20 through 29. Thematic dot maps showing the concentrations of cyanide in surface water in Rounds 1 through 4 are provided in Appendix M, Plates 1 through 4. Table 30 presents a comparison of concentrations of total and dissolved cyanide and free cyanide collected during Round 4. These data indicate the following:

- Total cyanide was detected in approximately 24% of all the samples collected during the surface water sampling. Total cyanide was detected in all three locations within the Backwater Seep Sampling Area (CFSWP-003, 004, and 005) during all four rounds of sampling. Outside of the Backwater Seep Sampling Area, total cyanide was detected in one location in the main stem of the Flathead River (CFSWP-006 at an estimated concentration of 3.2 µg/L) during Round 1, but was not detected in main stem of the Flathead River during Rounds 2 through 4. Total cyanide was detected in two locations within Cedar Creek (CFSWP-014 during Round 2 and CFSWP-015 during Rounds 1 and 2) with a maximum estimated concentration of 15.3 µg/L. Total cyanide was detected at two locations in the South Percolation Ponds (CFSWP-018 during Round 4 and CFSWP-020 during all four rounds) with a maximum concentration of 68.2 µg/L. Total cyanide was not detected in any surface water samples collected within the Cedar Creek Reservoir Drainage Overflow Ditch and the Northern Surface Water Area during the four rounds of sampling.

- At all locations where total cyanide was detected, concentrations of total cyanide exceed the USEPA Tapwater RSL of 0.15 µg/L. Total cyanide concentrations exceeded the DEQ-7 Human Health Standard of 140 µg/L and/or the USEPA MCL of 200 µg/L only in the Backwater Seep Sampling Area at sample location CFSWP-004 (209 µg/L during Round 1 and 178 µg/L during Round 2), and CFSWP-005 (213 µg/L during Round 1, 192 µg/L during Round 2, and 197 µg/L during Round 4).

- Total cyanide concentrations exceeded the DEQ-7 Acute Aquatic Life Standard of 22 µg/L in the Backwater Seep Sampling Area at sample locations CFSWP-003 (36.2 µg/L during Round 2), CFSWP-004 (209 µg/L during Round 1 and 178 µg/L during Round 2), and CFSWP-005 (213 µg/L during Round 1, 192 µg/L during Round 2, 24.7 µg/L during Round 3, and 197 µg/L during Round 4). Total cyanide concentrations exceeded the DEQ-7 Acute Aquatic Life Standard of 22 µg/L in one sample from the South Percolation Ponds at sample location CFSWP-018 (77.2 µg/L during Round 4 only).

- Total cyanide concentrations exceeded the DEQ-7 Chronic Aquatic Life Standard of 5.2 µg/L in the Backwater Seep Sampling Area at all three sample locations during all four rounds, ranging in concentration from 7.7 µg/L to 213 µg/L, with the maximum concentration in the Round 1 sample from CFSWP-005. Total cyanide concentrations

exceeded the DEQ-7 Chronic Aquatic Life Standard of 5.2 µg/L in Cedar Creek at sample location CFSWP-014 (15.3 µg/L in Round 2), and CFSWP-15 (10.6 µg/L in Round 2). Total cyanide concentrations exceeded the DEQ-7 Chronic Aquatic Life Standard of 5.2 µg/L in one sample from the South Percolation Ponds at sample location CFSWP-020 during all four rounds, ranging in concentration from 5.3 µg/L to 16.4 µg/L with the maximum concentration in the sample from Round 3. Total cyanide concentrations exceeded the DEQ-7 Chronic Aquatic Life Standard of 5.2 µg/L in the North Percolation Pond at sample location CFSWP-023 with a concentration of 7.6 µg/L in Round 3. All sample locations with concentrations exceeding the DEQ-7 Chronic Aquatic Life Standard of 5.2 µg/L also exceeded the Minimum ESV of 5 µg/L.

- As discussed in Section 3.4.6, free cyanide was added to the sampling scope of work for Rounds 3 and 4. During both of these rounds, free cyanide was detected in the Backwater Seep Sampling Area. The maximum concentration of free cyanide was 45.6 µg/L at location CFSWP-005 during Round 4. Free cyanide did not exceed the DEQ-7 Human Health Standard of 140 µg/L / USEPA MCL of 200 µg/L in any surface water samples. In each location where free cyanide was detected, it exceeded the USEPA Tapwater RSL of 0.15 µg/L.

- Free cyanide concentrations exceeded the DEQ-7 Acute Aquatic Life Standard of 22 µg/L in the Backwater Seep Sampling Area at sample location CFSWP-005, with a concentration of 45.6 µg/L during Round 4. No other concentrations of free cyanide exceeded the DEQ-7 Acute Aquatic Life Standard.

- Free cyanide concentrations exceeded DEQ-7 Chronic Aquatic Life Standard of 5.2 µg/L in the Backwater Seep Sampling Area during different sampling rounds at all three locations, ranging in concentration from 5.4 µg/L to 45.6 µg/L, with the maximum concentration in the Round 4 sample from CFSWP-005. Free cyanide concentrations exceeded DEQ-7 Chronic Aquatic Life Standard of 5.2 µg/L in one sample from the South Percolation Ponds at sample location CFSWP-020 during Round 3 with a concentration of 9 µg/L. All sample locations with concentrations exceeding the DEQ-7 Chronic Aquatic Life Standard of 5.2 µg/L also exceeded the Minimum ESV of 5 µg/L for total cyanide.

- Concentrations of total and dissolved cyanide and free cyanide were similar, with the total concentrations in most instances being slightly higher than dissolved. Detected concentrations of free cyanide were less than detected concentrations of total cyanide at all locations.

5.3.2 Fluoride in Surface Water

The statistical summary of fluoride in surface water in Rounds 1 through 4 are shown in Tables 20 through 29. Thematic dot maps showing the concentrations of fluoride in surface water in Rounds 1 through 4 are provided in Appendix M, Plates 5 and 6. Table 30 presents a comparison of concentrations of total and dissolved fluoride collected during Round 4. These data indicate the following:

- Fluoride was detected in 100% of the surface water samples during all four rounds of sampling, which is expected based on background fluoride conditions in Montana (MDEQ, 2014). Concentrations of fluoride exceeded the USEPA Tapwater RSL of 80 µg/L in 85% of the samples collected during the four rounds of sampling. However, concentrations of fluoride only exceeded the DEQ-7 Human Health Standard / USEPA MCL of 4,000 µg/L in one sample collected from location CFSWP-024 (Northeast Percolation Pond) during Round 4 (22,400 µg/L). This location was dry during all other sampling rounds.

- Outside the North-East Percolation Pond, the highest concentrations of fluoride were observed during Round 1 at sample locations CFSWP-004 and CFSWP-005 within the Backwater Seep Sampling Area, at concentrations of 2,560 and 2,570 µg/L respectively, which are less than the DEQ-7 Human Health Standard / USEPA MCL of 4,000 µg/L.

- Fluoride was detected in all of the upstream samples including CFSWP-014 (Cedar Creek) at a maximum concentration of 137 µg/L during Round 4, CFSWP-013 (Cedar Creek Reservoir Drainage Overflow Ditch) at a maximum concentration of 473 µg/L during Round 2, and CFSWP-017 (Flathead River) at a maximum concentration of 119 µg/L during Round 4.

- Fluoride concentrations exceeded the Minimum ESV of 120 µg/L in 64% of the surface water samples collected during all four rounds (36% during Round 1, 58% during Round 2, 67% during Round 3, and 91% during Round 4). There is no DEQ-7 Acute Aquatic Life Standard or DEQ-7 Chronic Aquatic Life Standard for fluoride.

- Review of Table 30 shows that total and dissolved concentrations of fluoride were similar.

5.3.3 Metals in Surface Water

The statistical summary of metals in surface water in Rounds 1 through 4 are shown in Tables 20 through 29. Thematic dot maps showing the concentrations of select metals in surface water in Rounds 1 through 4 are provided in Appendix M, Plates 7 through 22. Table 30 presents a comparison of concentrations of total and dissolved metals exceeding DEQ-7 Human Health Standard / USEPA MCL screening levels collected during Round 4. These data indicate the following:

- Naturally occurring metals that were most frequently observed in groundwater samples were also detected most frequently in Site-wide surface water, including barium, calcium, magnesium, potassium, and sodium. Where metals were detected, concentrations of aluminum, antimony, arsenic, barium, cadmium, chromium, cobalt, iron, manganese, nickel, thallium, and vanadium exceed their respective USEPA Tapwater RSLs.

- Antimony and thallium were the only metals detected in surface water samples at concentrations exceeding their respective DEQ-7 Human Health Standard and/or USEPA MCL. Both exceedances occurred at sample location CFSWP-024 in the Northeast Percolation Pond during Round 4. Antimony was detected at a concentration of 7.7 µg/L, which exceeded the DEQ-7 Human Health Standard of 5.6 µg/L and the USEPA MCL of 6 µg/L. Thallium was detected at a concentration of 0.27 µg/L, which exceeded the DEQ-7 Human Health Standard of 0.24 µg/L. Zinc did not exceed the human health criteria, but was detected at a concentration of 537 µg/L at location CFSWP-024 during Round 4, which exceeded the DEQ-7 Aquatic Life Standard of 103 µg/L.

- Detected concentrations for dissolved metals including aluminum, cadmium, copper, and zinc exceeded their respective DEQ-7 Acute Aquatic Life Standards and DEQ-7 Chronic Aquatic Life Standards at a frequency of less than 5%. Detected concentrations for dissolved metals including aluminum, barium, cadmium, copper, iron, nickel, and zinc exceeded their respective Minimum ESVs.

- Review of Table 30 shows that total and dissolved concentrations of metals were similar, with the total concentrations in most instances being slightly higher than dissolved.

5.3.4 VOCs, SVOCs in Surface Water

The statistical summary of VOCs and SVOCs in surface water in Rounds 1 through 4 are shown in Tables 20 through 29. These data indicate the following:

- VOCs and SVOCs were analyzed as additional analyses on the three samples collected in the South Percolation Ponds during Round 1 (CFSWP-018, CFSWP-019, CFSWP-020) and the one sample collected in the North-East Percolation Pond during Round 4 (CFSWP-024), in accordance with the RI/FS Work Plan (Roux Associates, 2015a). Acetone and methylene chloride, which are both likely artifacts of the laboratory process, were detected at concentrations below all screening criteria. No other VOCs were detected in the four percolation pond samples.

- SVOCs (primarily polyaromatic hydrocarbon compounds [PAHs]) were detected in sample CFSWP-024 from the North-East Percolation Pond, at concentrations exceeding the DEQ-7 Human Health Standards for benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, chrysene and indeno[1,2,3-cd]pyrene. SVOCs were not detected in surface water in the South Percolation Ponds.

- Concentrations of benzo[a]anthracene, benzo[a]pyrene, fluoranthene, phenanthrene, and pyrene in sample CFSWP-024 from the North-East Percolation Pond were also detected at concentrations exceeding their respective Minimum ESVs. These SVOCs do not have DEQ-7 Acute Aquatic Life Standards or DEQ-7 Chronic Aquatic Life Standards.

5.3.5 PCBs and Pesticides in Surface Water

The statistical summary of polychlorinated biphenyls (PCBs) and pesticides in surface water in Rounds 1 through 4 are shown in Tables 20 through 29. These data indicate the following:

- There were no detections of PCBs or pesticides in any of the four percolation pond samples.

5.3.6 General Chemistry in Surface Water

General chemistry parameters including alkalinity, ammonia, chloride, hardness (as calcium carbonate), nitrate + nitrite (as nitrogen), orthophosphate (as phosphorus), sulfide, and sulfate were measured in surface water samples to obtain data that could be utilized in chemical fate and transport evaluations and modeling, if needed in the future as part of the RI/FS. General chemistry results were also compared to the standards and RSLs where available. The statistical summary of general chemistry results for surface water in Rounds 1 through 4 are shown in Tables 20 through 29. Thematic dot maps showing the concentrations of general chemistry results in surface water in Rounds 1 through 4 are provided in Appendix M, Plates 23 through 30. These data indicate the following:

- Nitrate + nitrite (as nitrogen) is the only general chemistry parameter with a DEQ-7 Human Health Standard / USEPA MCL (i.e., 10,000 µg/L). Nitrate + nitrite (as nitrogen) was detected in 52% of the surface water samples collected during the four rounds of sampling, but did not exceed the DEQ-7 Human Health Standard / EPA MCL of 10,000 µg/L. During Round 1, nitrate + nitrite (as nitrogen) was detected in 23% of surface water samples, with a maximum concentration of 1,680 µg/L in sample CFSWP-005 in the Backwater Seep Sampling Area. During Round 2, nitrate + nitrite (as nitrogen) was detected in 21% of surface water samples, with a maximum concentration of 1,620 in sample CFSWP-005 from the Backwater Seep Sampling Area. During Round 3, nitrate + nitrite (as nitrogen) was detected in 75% of surface water samples, with the maximum concentration of 273 µg/L in sample CFSWP-015 in Cedar Creek. During

Round 4, nitrate + nitrite (as nitrogen) was detected in 83% of surface water samples, with a maximum of 1,700 µg/L in sample CFSWP-018 from the South Percolation Ponds.

- Chloride is the only general chemistry parameter with a Minimum ESV screening level (i.e., 120,000 µg/L). Chloride did not exceed the Minimum ESV during Rounds 1 through 4 surface water sampling.

5.4 Seasonal Variability of Concentrations in Surface Water Samples

Concentrations of total cyanide and fluoride from the four surface water sampling rounds were tabulated for comparison to evaluate if COPC concentrations varied seasonally. For each analyte, the minimum and maximum concentrations were identified with their associated sampling round. The comparison table is provided as Table 31.

The seasonal data for fluoride indicate the minimum concentrations of fluoride most often occurred during Round 1 (Sept 2016) and the maximum concentrations of fluoride most often occurred during Round 4 (June 2017). The seasonal data for total cyanide indicate the minimum concentrations of total cyanide (when detected) most often occurred in Round 3 (March 2017) and the maximum concentrations of total cyanide (when detected), most often occurred in Round 2 (December 2016).

6.0 GEOCHEMICAL EVALUATION

This section discusses an evaluation of groundwater geochemistry and provides a summary of geochemical modeling that was completed to further evaluate the elevated pH conditions in certain monitoring wells as described in Section 4.3.1.1 and geochemistry in monitoring wells.

6.1 Piper Plots and Stiff Diagrams

Anion and cation concentrations determined from metals and general chemistry analyses in groundwater were plotted in Piper Plots and Stiff Diagrams to facilitate the evaluation of potential hydraulic flow and connectivity in the hydrogeologic regime and to further evaluate groundwater and surface water chemistry.

The cations and anions are shown by separate ternary plots in the Piper Plots. The apexes of the cation plot are calcium, magnesium, and sodium plus potassium cations. The apexes of the anion plot are sulfate, chloride, and carbonate plus bicarbonate anions. The two ternary plots are then projected to present a matrix transformation of a graph of the anions and cations. Piper Plots for groundwater and surface water are provided as Appendix N. Groundwater data from wells screened in the upper hydrogeologic unit were plotted separately from the wells screened below the upper hydrogeologic unit to assess if there was a relationship between the groundwater chemistry in the different water bearing zones. The distributions of major ions in Site groundwater are also illustrated through a set of Piper Plots on Figure 3.

The Piper Plots suggest that although groundwater in wells screened within the upper hydrogeologic unit is generally similar to wells screened below the upper hydrogeologic unit (i.e., the compositions of many of the samples from both datasets suggest a calcium bicarbonate water), some of the upper hydrogeologic unit wells appear to be relatively sodium-enriched. This pattern is particularly pronounced in a subset of samples collected in wells located near the landfills.

Stiff diagrams present segments proportional to each ion on either convergent or parallel half-lines and joining the ends, resulting in a polygon, where every line represents an ion or the sum of an anion and cation. Stiff diagrams for groundwater and surface water are provided as Appendix O.

A sample summary report for the general chemistry for monitoring wells and surface water are included as Appendix P. A summary of the general chemistry ion balance is provided as Appendix Q.

6.2 Geochemical Modeling

As noted in Section 4.3.1.1, a subset of monitoring wells was observed to have elevated pH values in groundwater (i.e., above pH 10). Elevated concentrations of calcium in these wells suggest reactions involving cement grout used in well construction is a possible cause of the elevated pH. To further evaluate the groundwater chemistry, geochemical modeling was performed utilizing USGS's pH Redox Equilibrium (in C language) (PHREEQC) geochemical model (Parkhurst and Appelo, 1999). A description of the analysis and the results of the geochemical modeling is provided in Appendix R. These results were used to evaluate whether the concentrations of cyanide and fluoride measured in the wells could be affected by the elevated pH conditions.

Wells yielding samples that are characterized by elevated pH (i.e., above 10) reflect chemical reactions involving the cement used in well construction. Overall, the speciation modeling revealed no evidence indicating phenomena that could reduce the concentrations of either cyanide or fluoride under the elevated pH conditions encountered in some monitoring wells. These findings confirm that the data from these wells are acceptable for monitoring of groundwater quality conditions at the Site.

7.0 PROJECT DATA VERIFICATION AND VALIDATION SUMMARY OF FINDINGS

Data verification and validation were performed to confirm that the project data met the data quality objectives (DQOs) outlined in the RI/FS Work Plan (Roux Associates, 2015a) and Phase I SAP (Roux Associates, 2015b). The following section describes the verification and validation procedures performed as part of the Phase I Site Characterization groundwater and surface water sampling.

Data verification was performed by Roux Associates to evaluate the completeness, correctness, and conformance/compliance of data against the specifications outlined in the RI/FS Work Plan (Roux Associates, 2015a) and Phase I SAP (Roux Associates, 2015b); and to evaluate how closely the procedures outlined in the RI/FS Work Plan (Roux Associates, 2015a) and Phase I SAP (Roux Associates, 2015b) were followed during data generation. Personnel involved in the collection of samples and generation of data, including field samplers and subcontractors, conducted initial verification of field data. Field data verification included ensuring that data was properly collected and handled according to the sampling procedures described in the SAP and the SOPs. Documents outlining project procedures, including the RI/FS Work Plan (Roux Associates, 2015a), Phase I SAP (Roux Associates, 2015b), and task-specific SOPs, were readily available to all project personnel for the duration of the Phase I Site Characterization groundwater and surface water sampling. All records were verified with multiple tiers of review by field staff, RI Project Manager, and Quality Assurance (QA) Officer, including, but not limited to, chains of custody, field notebooks, field forms, and daily reports.

Prior to data validation, sample receipts, sample logins, and sample analysis methods were reviewed and verified. Laboratory data were reviewed by Laboratory Data Consultants, Inc. of Carlsbad, California, a qualified, third-party data validator. Validation of laboratory data was performed in accordance with the following USEPA guidance:

- *National Functional Guidelines for Organic Data Review* (USEPA, 2014a);
- *National Functional Guidelines for Inorganic Data Review* (USEPA, 2014b); and
- *Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use* (USEPA, 2009).

All laboratory data packages were verified and validated using a Stage 4 validation to evaluate whether the data meet the performance and acceptance criteria. The Stage 4 validation was performed on 100% of the laboratory data generated during the RI/FS. As described in the guidance (USEPA, 2009), the Stage 4 verification and validation included completeness and compliance checks of sample receipt conditions, both sample-related and instrument-related Quality Control (QC) results, recalculation checks, and the review of actual instrument outputs. The analytical results were evaluated with respect to the following data quality indicators: precision, accuracy, representativeness, completeness, sensitivity, and comparability.

The data validator documented all findings by adding appropriate validation qualifiers (as necessary) to the sample results in the laboratory data packages based on the various verification and validation tasks. The following qualifiers were applied to the data where applicable to identify data limitations identified during validation:

J+ ..... (Estimated, High Bias): The compound or analyte was analyzed for and positively identified by the laboratory; however, the reported concentration is estimated, displaying high bias, due to non-conformances discovered during data validation.

J- ..... (Estimated, Low Bias): The compound or analyte was analyzed for and positively identified by the laboratory; however, the reported concentration is estimated, displaying low bias, due to non-conformances discovered during data validation.

J ..... (Estimated, Bias Indeterminate): The compound or analyte was analyzed for and positively identified by the laboratory; however, the reported concentration is estimated due to it being below the laboratory quantitation limit or due to non-conformances discovered during data validation. Bias is indeterminate.

U ..... (Non-detected): The compound or analyte was analyzed for and positively identified by the laboratory; however, the compound or analyte should be considered non-detect at the reported concentration due to the presence of contaminants detected in the associated blank(s).

UJ ..... (Non-detected estimated): The compound or analyte was reported as not detected by the laboratory; however, the reported quantitation/detection limit is estimated due to non-conformances discovered during data validation.

R ..... (Rejected): The sample results were rejected due to gross non-conformances discovered during data validation. Data qualified as rejected is not usable.

NA..... (Not Applicable): The non-conformances discovered during data validation demonstrates a high bias, while the affected compound or analyte in the associated sample(s) was reported as not detected by the laboratory and did not warrant a qualification of the data.

Additionally, flags classified as P (Protocol) or A (Advisory) to indicate whether the flag is due to a laboratory deviation from a specified protocol or is of technical advisory nature.

7.1 Summary of Data Verification and Validation Results

Sample counts proposed in the Phase I SAP (Roux Associates, 2015b) were compared to groundwater and surface water samples collected during the Phase I Site Characterization. A summary count of all groundwater and surface water samples collected, not including field duplicates or Quality Assurance/Quality Control (QA/QC) samples, are included in the table below. Deviations from the proposed sample count provided in the Phase I SAP (Roux Associates, 2015b) and Phase I SAP Addendum (Roux Associates, 2016a) are also described in the table below.

Sample Type	Sample Quantity Proposed in Phase I SAP and/or SAP Addendum	Sample Quantity Collected Rounds 1 – 4	Notes
Surface Water	96	87	Two locations were dry during the Round; 1 sampling event; Seven locations were dry during the Round 2 sampling event and CFSWP-025 was collected as an opportunity sample; One location was dry during the Round 3 sampling event and CFSWP-025 was collected as an opportunity sample; and Two locations were dry during the Round 4 sampling event and CFSWP-025 was collected as an opportunity sample.
Groundwater	256	242	Four monitoring wells were dry during the Round 1 sampling event; Six monitoring wells were dry during the Round 2 sampling event; Three monitoring wells were dry during the Round 3 sampling event; and One monitoring well was dry during the Round 4 sampling event.

Approximately 54 laboratory sample delivery groups were submitted to Laboratory Data Consultants, Inc. for review as part of the data validation process. The results of the data

validation are summarized in data validation reports (Appendix S) produced by Laboratory Data Consultants, Inc. Data qualifiers added as a result of the data validation processes were imported to the CFAC RI/FS database and are included in the data summary tables in this GW/SW Data Summary Report.

A review of the data validation reports was completed by Roux Associates to evaluate the completeness of the data in accordance with the Phase I SAP (Roux Associates, 2015b) QA/QC procedures. Overall, approximately 42 analyses were rejected out of an estimated 32,937 analyses (approximately 1%) performed as part of the sampling activities summarized in this GW/SW Data Summary Report. This suggests that the overall data set generated during the work is usable and complete.

A summary of the data that was described in the data validation reports as rejected during the validation process is provided below. The analytical results that were rejected during data validation are not reliable and were thus excluded from the data evaluations described throughout this GW/SW Data Summary Report.

Groundwater Samples

Round 1

- Pentachlorophenol was rejected in 17 samples because laboratory control samples percent recovery was not within QC limits.
- Orthophosphate was rejected in 11 samples due to Matrix Spike/Matrix Spike Duplicate (MS/MSD) percent recovery not within QC limits.

Round 2

- 3,3'-Dichlorobenzidine, 3-nitroaniline, and 4-nitroaniline were rejected in one sample due to MS/MSD percent recovery not within QC limits.

Round 3

- No results were rejected in Round 3 groundwater samples.

Round 4

- Orthophosphate was rejected in six samples due to MS/MSD percent recovery not within QC limits.

Surface Water Samples

Round 1

- Orthophosphate was rejected in five samples due to MS/MSD percent recovery not within QC limits.

Round 2

- No results were rejected in Round 2 surface water samples.

Round 3

- No results were rejected in Round 3 surface water samples.

Round 4

- No results were rejected in Round 4 surface water samples.

Based on the evaluation of the data rejections, no gaps were identified in the data. The most commonly rejected analytes include orthophosphaste and pentachlorophenol. As these are not key COPCs identified, these rejections should not be considered a data gap that requires corrective action with the laboratory.

7.2 Evaluation of Method Detection Limits

A review of analytical method detection limits achieved by the laboratory in groundwater and surface water samples that were non-detect during the Phase I Site Characterization program was performed to evaluate the adequacy of the method detection limits relative to the various human health screening criteria. Tables providing minimum, maximum, mean, and median detection limits for all non-detect analytes in groundwater and surface water compared to all screening criteria are provided in Appendix T. The method detection limit summary tables indicate the following about the limits achieved for groundwater and surface water.

Groundwater

- The mean and median of all method detection limits achieved in all non-detect groundwater samples is greater than the lowest screening criteria (i.e., USEPA Tapwater RSLs) for 22% of all analytes (39 out of 181 analytes).

- The mean and median of all method detection limits achieved in all non-detect groundwater samples exceeds the MDEQ Circular 7 standards for 6% of all analytes (10 of 181 analytes).

- The mean and median of all method detection limits achieved in all non-detect groundwater samples exceeds the USEPA MCLs for 1% of all analytes (2 of 181 analytes, including pentachlorophenol and 1,2-dibromo-3-chloropropane).

Surface Water

- The mean and median of all method detection limits achieved in all in all non-detect surface water samples is greater than the lowest screening criteria (i.e., USEPA Tapwater RSLs) for 27% of all analytes (57 out of 211 analytes).

- The mean and median of all method detection limits achieved in all non-detect groundwater samples exceeds the MDEQ Circular 7 standards for 16% of all analytes (34 of 211 analytes).

- The mean and median of all method detection limits achieved in all non-detect groundwater samples exceeds the USEPA MCLs for 1% of all analytes (2 of 211 analytes, including pentachlorophenol and 1,2-dibromo-3-chloropropane).

- The mean and median of all method detection limits achieved in all non-detect groundwater samples exceeds the MDEQ Circular 7 Acute Aquatic Life Standards for 2% of all analytes (4 of 211 analytes, including total and dissolved silver and cadmium).

- The mean of all method detection limits achieved in all non-detect groundwater samples exceeds the MDEQ Circular 7 Chronic Aquatic Life Standards for 33% of all analytes (70 of 211 analytes).

- The median of all method detection limits achieved in all non-detect groundwater samples exceeds the MDEQ Circular 7 Chronic Aquatic Life Standards for 34% of all analytes (71 of 211 analytes).

- The mean and median of all method detection limits achieved in all in all non-detect surface water samples is greater than the lowest ecological screening criteria (i.e., Minimum ESV) for 41% of all analytes (86 out of 211 analytes).

Overall, the evaluation of method detection limits indicates that the method detection limits for non-detect results are sometimes above the lowest screening criteria (i.e., the USEPA Tapwater RSLs or Minimum ESV), for multiple analytes including COPCs such as cyanide. As noted above, these RSLs are designed to be conservative screening levels, and these RSLs are often not attainable in the laboratory. However, the method detection limits are almost always adequate for the other screening levels evaluated during the four rounds of groundwater and surface water sampling. It should be noted that during scoping of the RI/FS, CFAC and Roux Associates required that each laboratory being considered for use on the project provide a list of attainable method detection limits. During the analytical laboratory selection process, Roux Associates

evaluated the proposed method detection limits against the desired limits based on the screening criteria. This information was provided in the Phase I SAP (Roux Associates, 2015b) and Phase I SAP Addendum (Roux Associates, 2016a). TestAmerica was selected to be the primary analytical laboratory primarily because of their ability to achieve the most desired detection limits of all laboratories considered.

8.0 SUMMARY OF FINDINGS AND CSM REVIEW

The Phase I Site Characterization Data Summary Report (Roux Associates, 2017a) concluded with a "Summary of Findings and Conceptual Site Model (CSM) Review" section. That section summarized the results of the soil and sediment sampling, and Round 1 of groundwater and surface water sampling, in the context of the an updated CSM for the Site. Because only one round of groundwater and surface water sampling had been completed at that time, the discussions regarding potential source areas, COPCs, and contaminant migration were identified as preliminary findings; to be further evaluated based upon the additional rounds of sampling specified in the Phase I SAP (Roux Associates, 2015b), and where necessary, Phase II Site Characterization activities. The majority of the preliminary CSM as it relates to groundwater and surface water has been confirmed by the additional three rounds of monitoring. The sections below provide a supplemental review and update of the CSM, now that all four rounds of sampling originally proposed in the Phase I SAP (Roux Associates, 2015b) have been completed. As stated in the RI/FS Work Plan (Roux Associates, 2015a), the CSM will be updated on an ongoing basis throughout the performance of the RI/FS.

8.1 Discussion of COPCs

This section provides an update on the COPCs in groundwater and surface water.

8.1.1 Groundwater

Cyanide and fluoride were identified as the primary COPCs in Site groundwater based on historical data collected at the Site and based on the Phase I Site Characterization Data. The sampling results described in this data summary report confirm cyanide and fluoride as the primary COPCs in groundwater, with elevated concentrations of both constituents observed in Site groundwater during all four rounds of sampling. The measured concentrations observed across the Site varied during each sampling round; however, the highest concentrations were generally observed near the same suspected source areas during each round (see discussion of source areas in Section 8.2). It should be noted that the average concentrations of fluoride reported for public water and community water supply wells in the in the Flathead Valley is estimated to be approximately 160 µg/L (MDEQ, 2014) and that some detections of fluoride within the Site are similar to concentrations measured in public and community water supply wells.

The four rounds of groundwater sampling confirmed that many naturally occurring metals were detected frequently in groundwater samples. The most commonly detected metals in groundwater in all four sampling rounds were barium, calcium, magnesium, potassium, and sodium, which were detected in 100% of groundwater samples. Arsenic, antimony, barium, and zinc were the only metals detected in groundwater samples at concentrations exceeding their respective DEQ-7 Human Health Standard and/or USEPA MCL. The exceedances were limited to one sampling location for each metal in each sampling round; except for arsenic which exceeded the USEPA MCL at a maximum of four locations during Round 4.

The four rounds of sampling also confirmed that VOCs and SVOCs were found infrequently in groundwater at the Site. VOCs and SVOCs were detected in less than 10% and 4% respectively, of all groundwater samples collected from monitoring wells screened in the upper hydrogeologic unit throughout the sampling. VOC and SVOC detections did not exceed DEQ-7 Human Health Standards / USEPA MCLs in any groundwater samples.

Consistent with the Round 1 results, PAHs were not detected in any groundwater samples collected during Rounds 2 thru 4. This confirms the preliminary finding from the Round 1, that PAHs observed in soil are not impacting groundwater quality.

8.1.2 Surface Water

Cyanide was identified as the primary COPC in Site Surface water in the CSM. Cyanide concentrations exceeded the DEQ-7 Human Health Standard and/or the USEPA MCL in the Backwater Seep Sampling Area during sampling Rounds 1, 2 and 4. Concentrations of cyanide measured in the Backwater Seep Sampling Area are consistent with historical data collected in the Backwater Seep Sampling Area as part of the Montana Pollutant Discharge Elimination system (MPDES) permit for the Site.

Cyanide was also detected in surface water in Cedar Creek, the North-West Percolation Pond, and the South Percolation ponds during the sampling efforts; however, concentrations did not exceed the DEQ-7 Human Health Standard and/or the USEPA MCL in any of these locations.

Similar to groundwater, the four rounds of surface water sampling confirmed that many naturally occurring metals were detected frequently in surface water samples. Antimony and thallium were the only metals detected in surface water samples at concentrations exceeding their respective DEQ-7 Human Health Standard and/or USEPA MCL, and both exceedances occurred at sample in the North-East Percolation Pond during Round 4.

VOCs and SVOCs were analyzed in samples collected from the North and South Percolation Ponds. Acetone and methylene chloride were the only VOCs detected in the samples from the ponds (at concentrations below all screening criteria), which are both likely artifacts of the laboratory process. SVOCs (primarily PAHs) were detected in the sample from the North-East Percolation Pond, at concentrations exceeding the DEQ-7 Human Health Standards for benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, chrysene and indeno[1,2,3-cd]pyrene. SVOCs were not detected in surface water in the South Percolation ponds.

8.2 Discussion of Potential Source Areas

This section provides an update on the potential source areas for COPCs in groundwater and surface water.

8.2.1 Groundwater

The Phase I Site Characterization Data Summary Report identified that the highest concentrations of cyanide and fluoride in groundwater in Round 1 of sampling were observed adjacent to, and/or downgradient of, the West Landfill, the Wet Scrubber Sludge Pond, and the Former Drum Storage Area. The data from Round 1 indicated that these Site features are the primary source of the elevated cyanide and fluoride concentrations in groundwater, which would be consistent with the historical use of these features as disposal locations for wastes containing cyanide and fluoride (i.e., cyanide in spent potliner (SPL) disposed in the West Landfill; and fluoride within the calcium fluoride sludge disposed in Wet Scrubber Sludge Pond), as well as with current understanding that both landfills are unlined.

As discussed in Section 4.3.2, Plates 7 and 10 show contours of cyanide and fluoride concentrations, respectively, in groundwater based on the four rounds of sampling. The contour maps indicate that highest cyanide and fluoride concentrations in groundwater appear to originate

adjacent to and downgradient of the Wet Scrubber Sludge Pond and the West Landfill consistently during all four rounds of sampling. These data further support that these Site features are the source area of elevated cyanide and fluoride concentrations in groundwater. Plates 7 also indicates variable concentrations of cyanide downgradient of the West Landfill / Wet Scrubber Sludge Pond, in the area located around the North-East Percolation Pond and to the west of the Main Plant Area.

Additionally, during Rounds 1 and 2, the monitoring well located at the Center Landfill (CFMW-017) did not have sufficient volume to collect a groundwater sample. However, groundwater samples collected from CFMW-017 during Rounds 3 and 4 indicate that concentrations of cyanide and fluoride are elevated in groundwater at this well location during both sampling rounds as compared to the surrounding wells. The concentrations indicate that the Center Landfill may also be a source area for the observed elevated cyanide and fluoride concentrations in groundwater.

The Phase I Site Characterization Data Summary Report also noted that the North-East Percolation Pond and North-West Percolation Pond are located hydraulically downgradient of the West Landfill and Wet Scrubber Sludge Pond source area, and that the concentrations of cyanide and fluoride in groundwater downgradient (south) of the ponds are less than those measured in wells upgradient of the ponds. Similar concentrations were observed upgradient and downgradient of the ponds during Rounds 2 through 4. The continued decrease in concentrations as groundwater flows beneath the ponds supports that, currently, the ponds are not a significant source of the cyanide and fluoride concentrations observed in groundwater (i.e., if the ponds were a significant source, an increase in cyanide and fluoride concentrations would be expected).

8.2.2 Surface Water

The Backwater Seep Sampling area is a location where groundwater is expressed from the upper hydrogeologic unit to the Flathead River. Historically, groundwater in this area has consistently been observed to discharge from the banks and has been sampled as part of the requirements for the Site MPDES Permit (#MT00300066). The hydrogeologic studies (i.e., groundwater elevation data and surface water elevation data) indicate that groundwater discharges to Flathead River. The elevated concentrations of cyanide measured in the Backwater Seep Sampling Area are

consistent with the observed concentrations of cyanide in groundwater for this area, as shown on the cyanide contour maps (Plate 7). These concentrations indicate the groundwater is the source of the cyanide concentrations measured in the Backwater Seep Sampling Area. Additionally, concentrations of cyanide up-river in the Flathead River were typically non-detect, further supporting that groundwater discharge is the source of the cyanide in the Backwater Seep Sampling Area.

As noted in the Phase I Data Summary Report, there was an isolated detection of cyanide in Cedar Creek surface water during Round 1. This was further investigated by adding an additional location slightly upstream and by conducting additional sampling in Rounds 2 through 4. In Round 2, cyanide was detected at two locations, including the original location and the most upstream location; however, cyanide was non-detect in Cedar Creek in Rounds 3 and 4. The maximum concentration measured in Cedar Creek during the four rounds of sampling was 15.3 µg/L. As documented in the Phase I Data Summary Report and this GW/SW Data Summary Report, Cedar Creek is not a groundwater discharge point. In addition, based upon site topography and field observations, there is no storm water runoff from the former operational areas of the Site to Cedar Creek. The sporadic and isolated detections of cyanide, including one detection at the upstream location, suggest that the detections may attributable to entrained sediment in the sample; as all of the samples with detections were unfiltered. During Round 4, both filtered and unfiltered samples were collected for analysis and all samples from Cedar Creek were non-detect for cyanide.

As noted in Section 8.1.2, the only concentrations of metals in surface water that exceeded their respective DEQ-7 Human Health Standard and/or USEPA MCL occurred in the North-East Percolation Pond sample. Additionally, SVOCs (primarily PAHs) were also detected in the surface water sample from the North-East Percolation Pond at concentrations exceeding the DEQ-7 Human Health Standards. Based on Site reconnaissance and observations during drilling (black, coal tar pitch soil/sediment), and based on the elevated levels of PAHs observed in soil samples (as described in the Phase I Site Characterization), it's likely that the soils/sediments within the pond are the source of the COPCs in the surface water from the pond.

8.3 Migration of COPCs from Source Areas

This section provides an update on the migration of COPCs in groundwater and surface water.

8.3.1 Groundwater

As described above, the four rounds of groundwater sampling indicate that the West Landfill, Wet Scrubber Sludge Pond, the Former Drum Storage Area, and the Center Landfill appear to be the primary sources of the cyanide and fluoride in groundwater.

As shown in Plates 7 and 10, impacted groundwater in the upper hydrogeologic unit appears to generally migrate southward from the sources areas, and flow towards the Flathead River. Cyanide concentrations above 200 µg/L (USEPA MCL) extend as far south as the Flathead River during all four rounds. These concentrations of cyanide are consistent with similarly observed concentrations of cyanide in surface water from the Backwater Seep Sampling Area of the Flathead River, which is a location where groundwater is expressed from the upper hydrogeologic unit to the Flathead River.

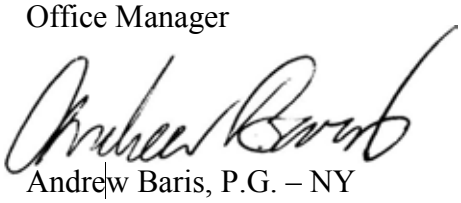
Cyanide and fluoride concentrations measured in monitoring wells outside of the contours shown on Plates 7 and 10 are less than half of the MCL in all four rounds of sampling. Cyanide and fluoride concentrations are non-detect in the north, west and southwest portions of the Site (e.g., near Aluminum City) during all four rounds of sampling. The data support that migration of the cyanide and fluoride is not in the direction towards Aluminum City, but rather follows the southerly groundwater flow patterns towards the Flathead River as depicted during all four rounds of groundwater elevation gauging (Plates 3 through 6).

The cyanide and fluoride contour maps were also utilized to evaluate groundwater quality conditions upgradient and downgradient of the Main Plant Area and the North Percolation Ponds. The data indicates variable concentrations of cyanide downgradient of the West Landfill / Wet Scrubber Sludge Pond, in the area located around the North-East Percolation Pond and to the west of the Main Plant buildings. Immediately south and southwest of the NE Percolation Pond, an area of lower cyanide concentrations is typically observed. The lower concentrations may be attributable to increased recharge to the upper hydrogeologic unit in this area; as all storm water from the concrete covered main plant area is directed into the NE Pond. The size of the lower concentration area varies from round to round, but appears largest (as delineated by the closed

300 µg/l contour) in the June 2017 sampling event. The contour maps for all four rounds indicate no increase in concentrations in monitoring wells located downgradient of the Main Plant.

During all four rounds of sampling, the cyanide and fluoride concentrations in groundwater decrease with depth within the upper hydrogeologic unit, and concentrations were generally non-detect in monitoring wells screened below the upper hydrogeologic unit. These non-detect findings indicate there is limited vertical migration and that the cyanide and fluoride are primarily migrating horizontally within the upper hydrogeologic unit. These findings are consistent with observed hydrogeologic conditions described in Sections 4.1 and 4.2, which indicate that there is only limited, if any, hydraulic connectivity between the upper hydrogeologic unit and the water bearing zones screened in the underlying glacial till.

8.3.2. Surface Water



As noted in Section 8.2.2, the Backwater Seep Sampling Area is a location where groundwater is expressed from the upper hydrogeologic unit to the Flathead River, and thus the source of the COPCs in the Backwater Seep Sampling Area is the groundwater. This groundwater likely originates in the West Landfill/Wet Scrubber Sludge Pond area and migrates south towards the Backwater Seep Sampling Area, as described in Section 8.3.1. All samples collected within the main stem of the Flathead River downgradient of the Backwater Seep Sampling Area during all four rounds of sampling were non-detect for cyanide. These findings confirm the preliminary CSM, that the elevated levels of cyanide and fluoride found in groundwater, the Backwater Seep Sampling Area, and the South Percolation Ponds, are not impacting surface water quality within the main channel of the Flathead River.

Bolding indicates an exceedance of DEQ-7 Human Health Standards
Shading indicates an exceedance of EPA Drinking Water MCLs
Red indicates an exceedance of EPA Tapwater RSLs

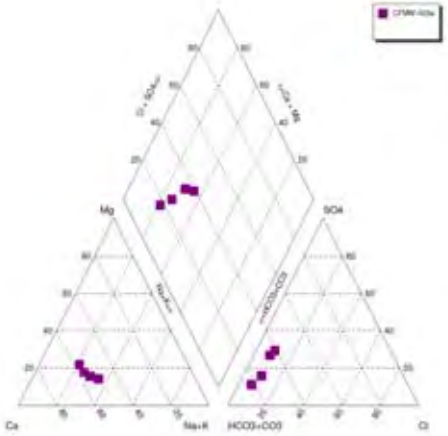
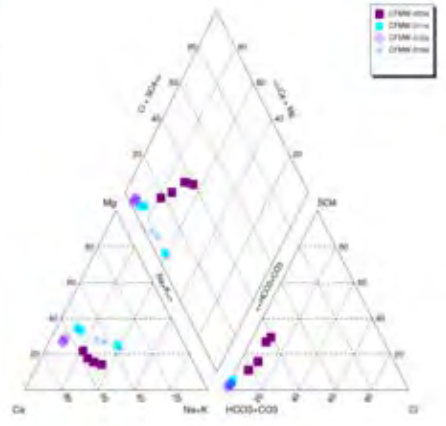
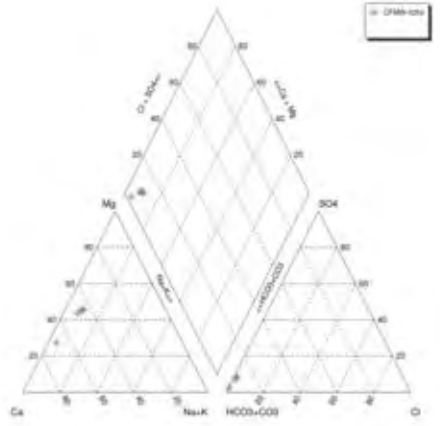
UU, adjacent to landfills



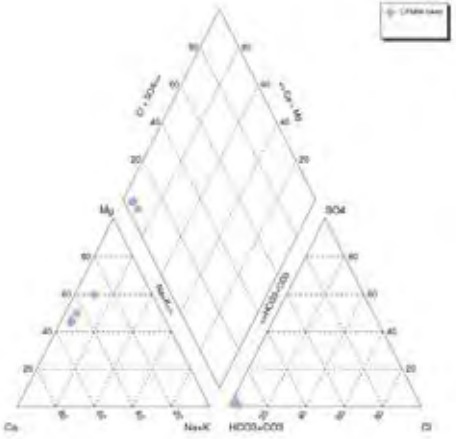
UU, in greater landfill area



UU, downgradient of landfill



UU, near main plant



BUU, adjacent to landfills

BUU, in greater landfill area

BUU, downgradient of landfill

BUU, near main plant

Figure 3. Piper diagrams illustrating the proportions of major ion concentrations in various subsets of Site groundwater; UU refers to monitoring wells screened in the upper hydrogeologic unit and BUU refers to monitoring wells screened below the upper hydrogeologic unit, respectively. Only wells with pH values less than 10 and ion balances less than 20% are shown.

APPENDICES

(Provided on CD in Bound Copy)

A. USGS Flathead River Station Discharge and Elevation Graphs
    1. Flathead River Average Annual Daily Discharge (1952 to 2017)
    2. Flathead River Average Daily Discharge and Elevation (April 2016 to June 2017)

B. Hydrographs from Long Term Pressure Transducer Data

C. Field Data Sheets
    1. Groundwater Sample Field Data Sheets
    2. Surface Water Sample Field Data Sheets
    3. Slug Testing Field Data Sheets

D. Surface Water Discharge Calculations

E. Executed Record of Modification Forms

F. Investigation Derived Waste Water Manifests and Sample Results

G. Groundwater Laboratory Analytical Data Tables – Rounds 1 through 4
    1. VOCs in Groundwater
    2. SVOCs in Groundwater
    3. Metals in Groundwater
    4. General Chemistry in Groundwater

H. Groundwater Thematic Maps – Rounds 1 through 4
    1. Concentrations of Total Cyanide in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
    2. Concentrations of Total Free Cyanide Rounds 3 and 4 in Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
    3. Concentrations of Dissolved Cyanide in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit

4. Concentrations of Dissolved Free Cyanide in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
5. Concentrations of Total Fluoride in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
6. Concentrations of Dissolved Fluoride in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
7. Concentrations of Total Aluminum in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
8. Concentrations of Total Arsenic in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
9. Concentrations of Total Cobalt in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
10. Concentrations of Total Copper in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
11. Concentrations of Total Iron in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
12. Concentrations of Total Lead in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
13. Concentrations of Total Manganese in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
14. Concentrations of Total Thallium in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
15. Concentrations of Dissolved Aluminum in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
16. Concentrations of Dissolved Arsenic in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
17. Concentrations of Dissolved Cobalt in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
18. Concentrations of Dissolved Copper in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit

19. Concentrations of Dissolved Iron in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
20. Concentrations of Dissolved Lead in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
21. Concentrations of Dissolved Manganese in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
22. Concentrations of Dissolved Thallium in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
23. Concentrations of Total Cyanide in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
24. Concentrations of Total Free Cyanide in Rounds 3 and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
25. Concentrations of Dissolved Cyanide in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
26. Concentrations of Dissolved Free Cyanide in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
27. Concentrations of Total Fluoride in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
28. Concentrations of Dissolved Fluoride in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
29. Concentrations of Total Aluminum in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
30. Concentrations of Total Arsenic in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
31. Concentrations of Total Cobalt in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
32. Concentrations of Total Copper in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
33. Concentrations of Total Iron in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
34. Concentrations of Total Lead in Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit

35. Concentrations of Total Manganese in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
36. Concentrations of Total Thallium in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
37. Concentrations of Dissolved Aluminum in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
38. Concentrations of Dissolved Arsenic in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
39. Concentrations of Dissolved Cobalt in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
40. Concentrations of Dissolved Copper in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
41. Concentrations of Dissolved Iron in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
42. Concentrations of Dissolved Lead in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
43. Concentrations of Dissolved Manganese in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
44. Concentrations of Dissolved Thallium in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
45. Concentrations of Alkalinity in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
46. Concentrations of Ammonia in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
47. Concentrations of Chloride in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
48. Concentrations of Hardness as Calcium Carbonate in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
49. Concentrations of Nitrate and Nitrite in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
50. Concentrations of Orthophosphate in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit

51. Concentrations of Sulfate in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
52. Concentrations of Alkalinity in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
53. Concentrations of Ammonia in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
54. Concentrations of Chloride in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
55. Concentrations of Total Hardness as Calcium Carbonate in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
56. Concentrations of Total Nitrate and Nitrite in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
57. Concentrations of Orthophosphate in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit

Time: 930

DTW: 64.04
DTB: 99.36
Depth to Top of Screen: 89.36
Depth to Bottom of Screen: 99.36

Pneumatic or Mechanical Test Performed: mechanical

Head Displacement of 1 foot

Test 1:

Actual Head Displacement:
Depth of Transducer below static water level:
File Name:

Notes: 11:00 -1.26
12.25 - 0.818
14:05 -0.460
16.00 -0.202
7/26 13:10 +0.559

Test 2:

Actual Head Displacement:
Depth of Transducer below static water level:
File Name:

Notes:

Head Displacement of 2 feet

Test 1:

Actual Head Displacement: 2.01
Depth of Transducer below static water level: ~10.0
File Name: CFMW-008a-MST

Notes: Used troll datalogger. TOOK ~9 hours to return to baseline pressure.

Completed test 1 7/24/17

Test 2:

Actual Head Displacement: 1.97
Depth of Transducer below static water level: ~9.5
File Name: CFMW-008a-MST2

Notes: Test 2 started 7/25/17 @ 12:30
1530. -0.907
Pulled up slug to produce head drop 7/26
1730: -0.86

Slug Testing Sheet

DTB: 52.79

Depth to Top of Screen: 42.79

Depth to Bottom of Screen: 52.79

Pneumatic or Mechanical Test Performed:

Head Displacement of 1 foot

Test 1:

Actual Head Displacement: 0.9'

Depth of Transducer below static water level: 3.03'

File Name: MW-011-11

Notes: pressure 15" H_2O

Test 2:

Actual Head Displacement: 0.5'

Depth of Transducer below static water level: 3.03'

File Name: MW011-12

Notes: leak created after first test (water down hole?)

Test 3: Head Δ 1.0 — oscillating
Depth: 3.0
Filename: MW011-13

Test 4: Head Δ: 0.9 oscillating
Depth: 3.0
Filename: MW011-14

Head Displacement of 2 feet

Test 1:

Actual Head Displacement: 2.0

Depth of Transducer below static water level: 3.0

File Name: MW011-21

Notes: ~~Unable to apply pressure > 30" H_2O, can't perform 2 ft test~~ (SW)

Able to redo test
- oscillating
- underdampened

Test 2:

Actual Head Displacement: 2.0

Depth of Transducer below static water level: 3.0

File Name: MW-011-22

Notes: Some oscillations possibly underdampened

Executed Record of Modification Forms

Record of Modification

Phase 1 Site Characterization Sampling and Analysis Plan Field Activities
Columbia Fall Aluminum Company RI/FS
Phase 1 SAP MOD #8

Instructions to Requester: **Submit to Roux RI Manager or Roux RI/FS Project Manager**
Roux RI Manager will maintain legible copies in a binder that can be accessed by personnel.

Project Work Plan/QAPP (check one):

[X] 2015 Phase 1 SAP

[ ] SOP (Title, # and approval date): _____

Requester: Michael Ritorto, RI Manager Date: 8/30/2016

Applicable section of SAP/SOP:

SAP Section 4.9: Surface Water and Sediment Sampling

Description of Modification:

Selected surface water and sediment sample locations within the Flathead River will be sampled via boat. When sampling from the boat, a ponar dredge sampling device and/or other hand tools will be utilized to collect the sample in accordance with Roux SOP 5.2 that was provided in the Phase I SAP. The boat and captain will be provided by Kennedy/Jenks Consulting (Whitefish, Montana). Kennedy/Jenks Consulting is new subcontractor to the project and will be working as a subcontractor to Roux Associates.

During use of the boat, Roux Associates and Kennedy/Jenks personnel will implement safe boating practices including use of a personal flotation devices and spotting of sampling personnel while sampling. Additionally, all personnel involved with the sampling will review the Job Hazard Analysis for boating activities provided by Kennedy/Jenks (see attached). A tailgate meeting will also be held before the boating event and potential hazards and mitigative actions will be discussed.

Rationale for Modifications / Potential Implications of Modifications:

During the initial site reconnaissance, several surface water and sediment sample locations along the Flathead River were deemed inaccessible by foot due to the presence of forested areas and limited bank/shoreline for traversing. Use of a boat to access some of the sampling locations will provide easier and safer access to the sampling locations. The boat will also allow Roux Associates personnel the evaluate the sampling locations prior to sample collection and evaluate potential locations where sediment is present, if any.

Applicable section of SAP/SOP:

SAP Section 4.8 and 4.9: Groundwater and Surface Water Sampling

Description of Modification:

During the Phase I Site Characterization sampling event scheduled to begin in March 2017 (Sampling Round 3), selected surface water and groundwater samples will be analyzed for free cyanide via USEPA laboratory method 9016. These analyses are in addition to the total cyanide analyses that are included as part of the original scope of work.

Free cyanide analysis will be completed on samples from 46 monitoring wells and 5 surface water locations during the sampling event. These locations have been selected based on the sampling results of Round 1 and 2 for total cyanide analysis. At each of these locations, total cyanide was detected above the method detection limit in one or both of the first two rounds of sampling (September and November 2016).

Rationale for Modifications / Potential Implications of Modifications:

The various screening levels utilized to evaluate the Phase I Site Characterization data are based upon exposure to free cyanide. Thus, with the use of the total cyanide data, any potential for effects due to cyanide exposure is likely overestimated as free cyanide would only comprise a fraction, if any, of the total cyanide present. The analysis of free cyanide in the groundwater and surface water samples as proposed will further facilitate a better understanding of Site conditions.

Phase 1 Site Characterization Sampling and Analysis Plan Field Activities
Columbia Fall Aluminum Company RI/FS
Phase 1 SAP MOD #11

Instructions to Requester: **Submit to Roux RI Manager or Roux RI/FS Project Manager**
Roux RI Manager will maintain legible copies in a binder that can be accessed by personnel.

Project Work Plan/QAPP (check one):

[X] 2015 Phase 1 SAP

[ ] SOP (Title, # and approval date): _____

Requester: Michael Ritorto, RI Manager Date: June 12, 2017

Applicable section of SAP/SOP:

There is not an applicable section of the SAP/SOP because Slug Testing was not discussed in the Phase I SAP.

Description of Modification:

Roux Associates will complete slug tests at monitoring wells distributed across the Site. Pneumatic slug tests will be conducted on the new 2-inch diameter wells installed as part of the Phase I Site Characterization. For a pneumatic test to be conducted, the entire length of screen of the monitoring well must be submerged beneath the level of standing water in well. Mechanical slug tests will be conducted on the newly installed wells with partially submerged screens. Based upon water levels measured in July and August 2016, it is anticipated that approximately 38 of the 44 newly installed wells will be tested using the pneumatic method, and 6 of the 44 newly installed wells will be tested using the mechanical method; however, the final determination of wells to be tested will be made based upon water levels at the time the testing is to be performed.

Pneumatic slug tests will be conducted within the casing of each well using compressed air as the displacing (slug) volume. The water column within the well casing will be depressed by increasing the air pressure in the casing above the water column. When the water level is depressed to a predetermined level and the air pressure stabilized within the test interval, the air pressure within the well casing will be rapidly released. The instantaneous release of air pressure from the well casing will initiate a pneumatic slug withdrawal test, which will be recorded using a pressure transducer and a data logger. All tests will be conducted in accordance with the procedures outlined in the SOP titled "Standard Operating Procedure 4.8 for Conducting a Pneumatic Slug Test."

Mechanical slug tests will be conducted within the casing of each well using a solid cylinder (slug). Due

to the fact that mechanical slug tests are being performed on water table wells, the testing will be limited to "slug-out" tests. As part of the "slug-out test", the water column within the well casing will be decreasing by rapidly removing the solid slug from the water column. All changes in water levels will be recorded using a pressure transducer and a data logger. All tests will be conducted in accordance with the procedures outlined in the SOP titled "Standard Operating Procedure 4.9 for Conducting a Mechanical Slug Test."

At each location, the test will be conducted with an approximate 1-foot displacement. The test will be repeated at each well using 1-foot displacement to determine the reproducibility of the data. If water levels return to static or near static conditions within one hour, another test will be conducted using an approximate 2-foot displacement.

Data analysis to determine hydraulic conductivity values for each test will be performed using a combination of Excel, Aqtesolv or Geoprobe Slug Test Analysis software, and Win-Situ software. Following completion of testing and analysis, a report will be prepared to describe the tests and the data evaluation methods, and to summarize the test results. All data analysis procedures, including decision making processes, will be conducted in accordance with the procedures outlined in the SOP titled "Standard Operating Procedure 4.10 for "Analyzing Slug Test Data."

Rationale for Modifications / Potential Implications of Modifications:

The slug testing program will be performed to evaluate the *in situ* permeability contrast between various hydrogeologic units beneath the site. The slug tests will generate data that will be used to determine the hydraulic conductivity at each well as part of the ongoing Phase 1 Site Characterization program. The hydraulic conductivity data from each tested well will be added to the overall Phase I Site Characterization dataset and used for evaluation of groundwater flow beneath the Site.

CERTIFICATE OF DISPOSAL

CWM OF THE NORTHWEST, EPA ID: ORD089452353, has received waste material from COLUMBIA FALLS ALUMINUM CO on 05/12/17 as described on Shipping Document number 500842-17.

Profile Number: OR333862
CWM Tracking ID: 45329001
Process: EVAPORATION
Disposal Date: 05/12/17

I certify, on behalf of the above listed treatment facility, that to the best of my knowledge, the above-described waste was managed in compliance with all applicable laws, regulations, permits and licenses on the date listed above.

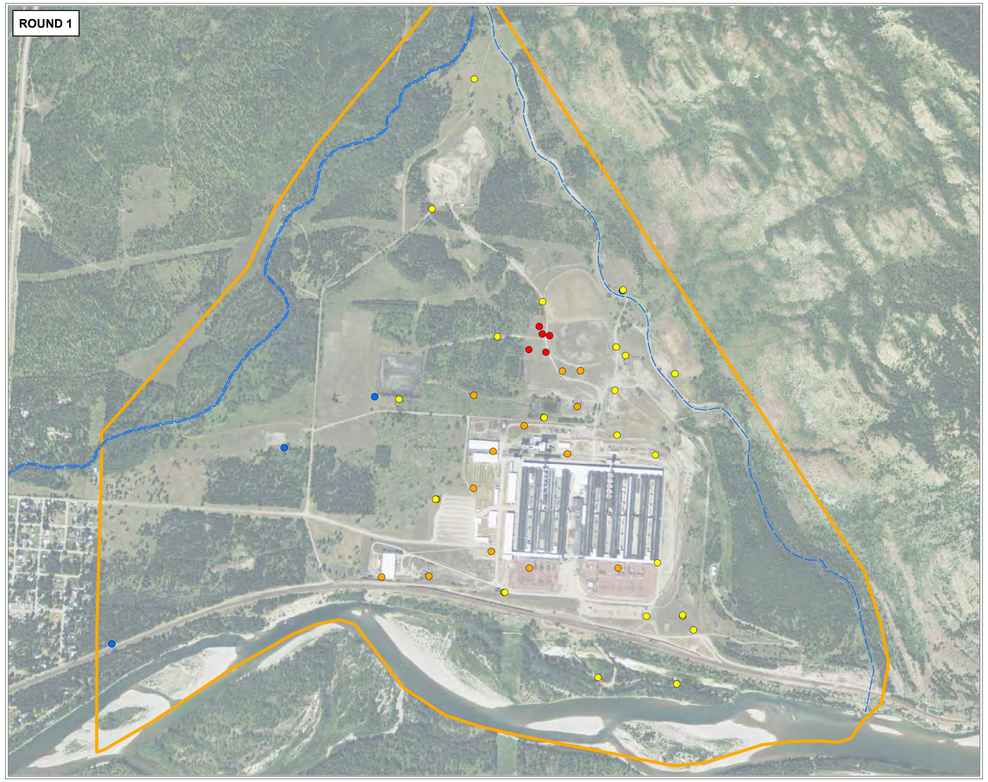
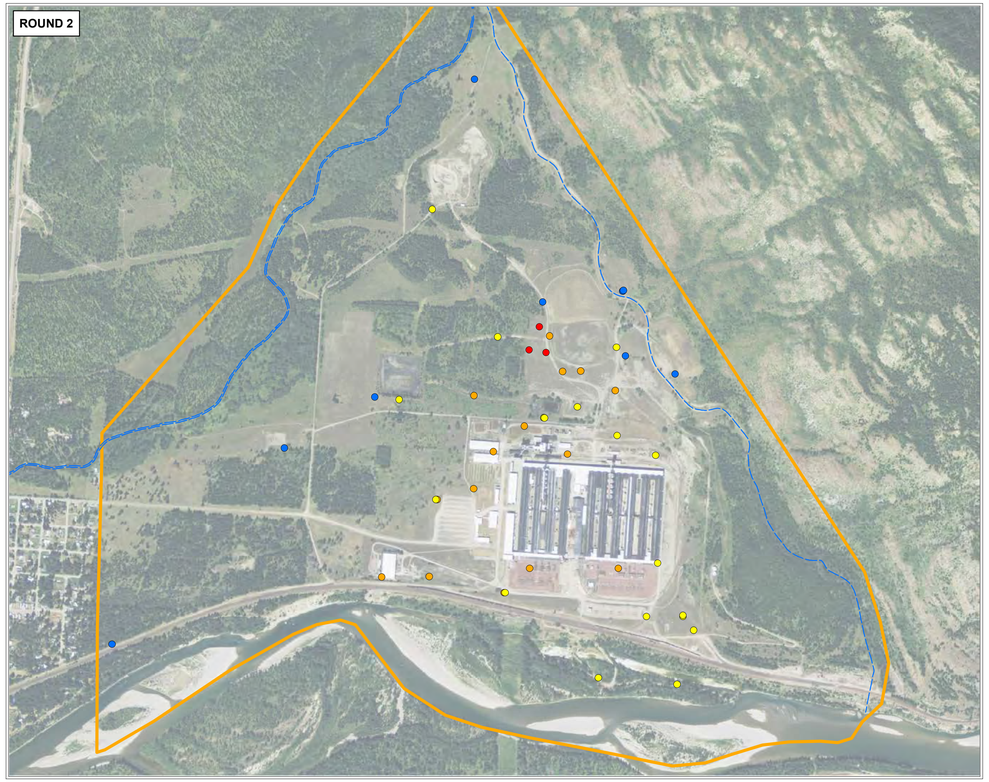
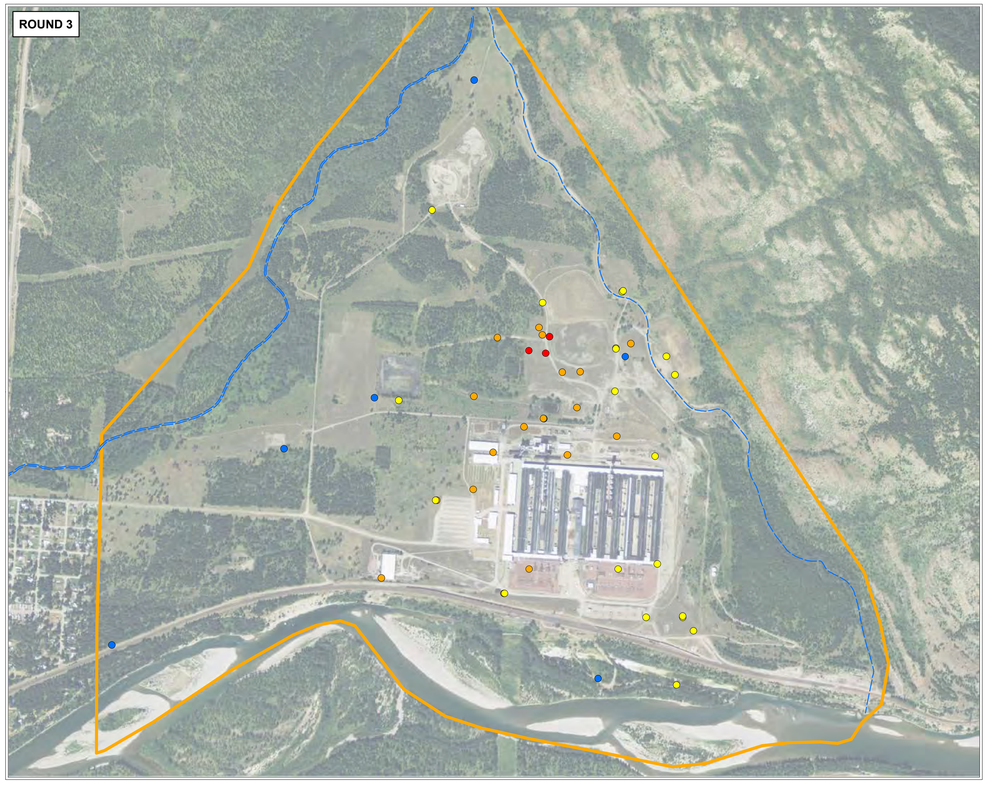
APPENDIX H



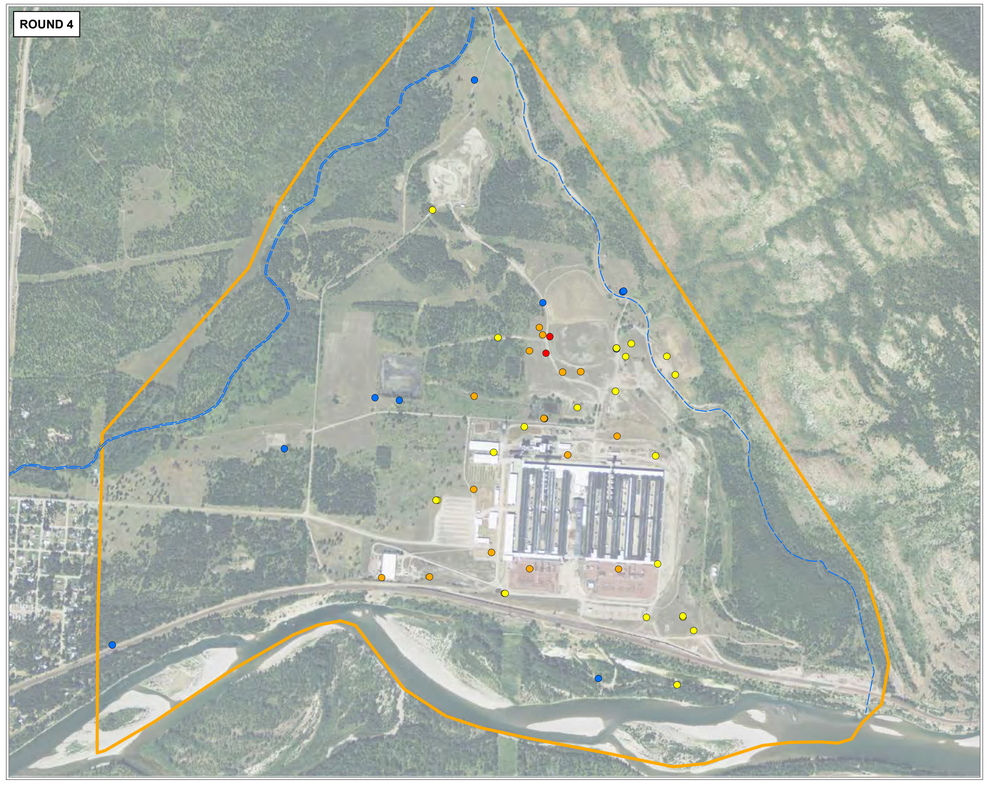
Groundwater Thematic Maps – Rounds 1 through 4



1. Concentrations of Total Cyanide in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
2. Concentrations of Total Free Cyanide Rounds 3 and 4 in Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
3. Concentrations of Dissolved Cyanide in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
4. Concentrations of Dissolved Free Cyanide in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
5. Concentrations of Total Fluoride in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
6. Concentrations of Dissolved Fluoride in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
7. Concentrations of Total Aluminum in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
8. Concentrations of Total Arsenic in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
9. Concentrations of Total Cobalt in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
10. Concentrations of Total Copper in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
11. Concentrations of Total Iron in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
12. Concentrations of Total Lead in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
13. Concentrations of Total Manganese in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
14. Concentrations of Total Thallium in Round 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit



15. Concentrations of Dissolved Aluminum in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
16. Concentrations of Dissolved Arsenic in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
17. Concentrations of Dissolved Cobalt in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
18. Concentrations of Dissolved Copper in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
19. Concentrations of Dissolved Iron in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
20. Concentrations of Dissolved Lead in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
21. Concentrations of Dissolved Manganese in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
22. Concentrations of Dissolved Thallium in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened in Upper Hydrogeologic Unit
23. Concentrations of Total Cyanide in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
24. Concentrations of Total Free Cyanide in Rounds 3 and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
25. Concentrations of Dissolved Cyanide in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
26. Concentrations of Dissolved Free Cyanide in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
27. Concentrations of Total Fluoride in Rounds 1,2,3, and 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
28. Concentrations of Dissolved Fluoride in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
29. Concentrations of Total Aluminum in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
30. Concentrations of Total Arsenic in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit



31. Concentrations of Total Cobalt in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
32. Concentrations of Total Copper in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
33. Concentrations of Total Iron in Round 4 Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit
34. Concentrations of Total Lead in Groundwater from Monitoring Wells Screened Below Upper Hydrogeologic Unit

EPA-OLEM VAPOR INTRUSION ASSESSMENT
Groundwater Concentration to Indoor Air Concentration (GWC-IAC) Calculator Version 3.5.1 (May 2016 RSLs)

Parameter	Symbol	Value	Instructions
Exposure Scenario	Scenario	Residential	Select residential or commercial scenario from pull down list
Target Risk for Carcinogens	TCR	1.00E-06	Enter target risk for carcinogens (for comparison to the calculated VI carcinogenic risk in column F)
Target Hazard Quotient for Non-Carcinogens	THQ	0.1	Enter target hazard quotient for non-carcinogens (for comparison to the calculated VI hazard in column G)
Average Groundwater Temperature (^{o}C)	Tgw	10.2	Enter average of the stabilized groundwater temperature to correct Henry's Law Constant for groundwater target concentrations

Notes:

(1) **Inhalation Pathway Exposure Parameters (RME):**

Exposure Scenario	Units	Residential Symbol	Residential Value	Commercial Symbol	Commercial Value	Selected (based on scenario) Symbol	Selected (based on scenario) Value
Averaging time for carcinogens	(yrs)	ATc_R_GW	70	ATc_C_GW	70	ATc_GW	70
Averaging time for non-carcinogens	(yrs)	ATnc_R_GW	26	ATnc_C_GW	25	Atnc_GW	26
Exposure duration	(yrs)	ED_R_GW	26	ED_C_GW	25	ED_GW	26
Exposure frequency	(days/yr)	EF_R_GW	350	EF_C_GW	250	EF_GW	350
Exposure time	(hr/day)	ET_R_GW	24	ET_C_GW	8	ET_GW	24

(2) **Generic Attenuation Factors:**

Source Medium of Vapors		Residential Symbol	Residential Value	Commercial Symbol	Commercial Value	Selected (based on scenario) Symbol	Selected (based on scenario) Value
Groundwater	(-)	AFgw_R_GW	0.001	AFgw_C_GW	0.001	AFgw_GW	0.001
Sub-Slab and Exterior Soil Gas	(-)	AFss_R_GW	0.03	AFss_C_GW	0.03	AFss_GW	0.03

(3) **Formulas**

Cia, target = MIN(Cia,c; Cia,nc)
Cia,c (ug/m3) = TCR x ATc x (365 days/yr) x (24 hrs/day) / (ED x EF x ET x IUR)
Cia,nc (ug/m3) = THQ x ATnc x (365 days/yr) x (24 hrs/day) x RfC x (1000 ug/mg) / (ED x EF x ET)

(4) **Special Case Chemicals**

	Residential Symbol	Residential Value	Commercial Symbol	Commercial Value	Selected (based on scenario) Symbol	Selected (based on scenario) Value
Trichloroethylene	mIURTCE_R_GW	1.00E-06	IURTCE_C_GW	0.00E+00	mIURTCE_GW	1.00E-06

Mutagenic Chemicals

Note: This section applies to trichloroethylene and other mutagenic chemicals, but not to vinyl chloride.

The exposure durations and age-dependent adjustment factors for mutagenic-mode-of-action are listed in the table below:

Age Cohort	Exposure Duration (years)	Age-dependent adjustment factor
0 - 2 years	2	10
2 - 6 years	4	3
6 - 16 years	10	3
16 - 26 years	10	1
Mutagenic-mode-of-action (MMOA) adjustment factor		72

This factor is used in the equations for mutagenic chemicals.

Vinyl Chloride

See the Navigation Guide equation for Cia,c for vinyl chloride.

Notation:
I = IRIS: EPA Integrated Risk Information System (IRIS). Available online at: http://www.epa.gov/iris/subst/index.html
P = PPRTV. EPA Provisional Peer Reviewed Toxicity Values (PPRTVs). Available online at: http://hhpprtv.ornl.gov/pprtv.shtml
A = Agency for Toxic Substances and Disease Registry (ATSDR) Minimum Risk Levels (MRLs). Available online at: http://www.atsdr.cdc.gov/mrls/index.html
CA = California Environmental Protection Agency/Office of Environmental Health Hazard Assessment assessments. Available online at: http://www.oehha.ca.gov/risk/ChemicalDB/index.asp
H = HEAST. EPA Superfund Health Effects Assessment Summary Tables (HEAST) database. Available online at: http://epa-heast.ornl.gov/heast.shtml
S = See RSL User Guide, Section 5
X = PPRTV Appendix
Mut = Chemical acts according to the mutagenic-mode-of-action, special exposure parameters apply (see footnote (4) above).
VC = Special exposure equation for vinyl chloride applies (see Navigation Guide for equation).
TCE = Special mutagenic and non-mutagenic IURs for trichloroethylene apply (see footnote (4) above).
Yellow highlighting indicates site-specific parameters that may be edited by the user.
Blue highlighting indicates exposure factors that are based on Risk Assessment Guidance for Superfund (RAGS) or EPA vapor intrusion guidance, which generally should not be changed.
Pink highlighting indicates VI carcinogenic risk greater than the target risk for carcinogens (TCR) or VI Hazard greater than or equal to the target hazard quotient for non-carcinogens (THQ).

Mutagenic Chemicals

Note: This section applies to trichloroethylene and other mutagenic chemicals, but not to vinyl chloride.

The exposure durations and age-dependent adjustment factors for mutagenic-mode-of-action are listed in the table below:

Age Cohort	Exposure Duration (years)	Age-dependent adjustment factor
0 - 2 years	2	10
2 - 6 years	4	3
6 - 16 years	10	3
16 - 26 years	10	1
Mutagenic-mode-of-action (MMOA) adjustment factor		72

This factor is used in the equations for mutagenic chemicals.

Vinyl Chloride

See the Navigation Guide equation for Cia,c for vinyl chloride.

Notation:
I = IRIS: EPA Integrated Risk Information System (IRIS). Available online at: http://www.epa.gov/iris/subst/index.html
P = PPRTV. EPA Provisional Peer Reviewed Toxicity Values (PPRTVs). Available online at: http://hhpprtv.ornl.gov/pprtv.shtml
A = Agency for Toxic Substances and Disease Registry (ATSDR) Minimum Risk Levels (MRLs). Available online at: http://www.atsdr.cdc.gov/mrls/index.html
CA = California Environmental Protection Agency/Office of Environmental Health Hazard Assessment assessments. Available online at: http://www.oehha.ca.gov/risk/ChemicalDB/index.asp
H = HEAST. EPA Superfund Health Effects Assessment Summary Tables (HEAST) database. Available online at: http://epa-heast.ornl.gov/heast.shtml
S = See RSL User Guide, Section 5
X = PPRTV Appendix
Mut = Chemical acts according to the mutagenic-mode-of-action, special exposure parameters apply (see footnote (4) above).
VC = Special exposure equation for vinyl chloride applies (see Navigation Guide for equation).
TCE = Special mutagenic and non-mutagenic IURs for trichloroethylene apply (see footnote (4) above).
Yellow highlighting indicates site-specific parameters that may be edited by the user.
Blue highlighting indicates exposure factors that are based on Risk Assessment Guidance for Superfund (RAGS) or EPA vapor intrusion guidance, which generally should not be changed.
Pink highlighting indicates VI carcinogenic risk greater than the target risk for carcinogens (TCR) or VI Hazard greater than or equal to the target hazard quotient for non-carcinogens (THQ).

EPA-OLEM VAPOR INTRUSION ASSESSMENT
Groundwater Concentration to Indoor Air Concentration (GWC-IAC) Calculator Version 3.5.1 (May 2016 RSLs)

Parameter	Symbol	Value	Instructions
Exposure Scenario	Scenario	Residential	Select residential or commercial scenario from pull down list
Target Risk for Carcinogens	TCR	1.00E-06	Enter target risk for carcinogens (for comparison to the calculated VI carcinogenic risk in column F)
Target Hazard Quotient for Non-Carcinogens	THQ	0.1	Enter target hazard quotient for non-carcinogens (for comparison to the calculated VI hazard in column G)
Average Groundwater Temperature (^{o}C)	Tgw	8	Enter average of the stabilized groundwater temperature to correct Henry's Law Constant for groundwater target concentrations

CAS	Chemical Name	Site Groundwater Concentration Cgw (ug/L)	Calculated Indoor Air Concentration Cia (ug/m^3)	VI Carcinogenic Risk CR	VI Hazard HQ	Inhalation Unit Risk IUR (ug/m^3)$^{-1}$	IUR Source*	Reference Concentration RfC (mg/m^3)	RFC Source*	Mutagenic Indicator i

Mutagenic Chemicals — The exposure durations and age-dependent adjustment factors for mutagenic-mode-of-action are listed in the table below:

Note: This section applies to trichloroethylene and other mutagenic chemicals, but not to vinyl chloride.

Age Cohort	Exposure Duration (years)	Age-dependent adjustment factor
0 - 2 years	2	10
2 - 6 years	4	3
6 - 16 years	10	3
16 - 26 years	10	1
Mutagenic-mode-of-action (MMOA) adjustment factor		72

This factor is used in the equations for mutagenic chemicals.

Vinyl Chloride — See the Navigation Guide equation for Cia,c for vinyl chloride.
