Acronyms

µg	micrograms
µmol/g_{OC}	micromoles per gram organic carbon
2,3,7,8-TCDD	2,3,7,8-tetrachlorodibenzo-p-dioxin
ANOVA	analysis of variance
AOC	Agreement and Order on Consent
AST	aboveground storage tank
ATP	adenosine triphosphate
AUF	area use factor
AVS	acid volatile sulfides
BAF	bioaccumulation factor
BCF	bioconcentration factor
BEHP	bis(2-ethylhexyl)phthalate
BERA	Baseline Ecological Risk Assessment
bgs	below ground surface
BLM	biotic ligand model
BSAF	biota-sediment accumulation factor
BTEX	benzene, toluene, ethylbenzene, and xylene
BTV	background threshold values
BW	body weight
CCC	criterion continuous concentration
CEC	cation exchange capacity
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
CFAC	Columbia Falls Aluminum Company, LLC
CMC	criteria maximum concentration
COPC	constituent of potential concern
COPEC	constituent of potential ecological concern
CSM	conceptual site model
DOC	dissolved organic carbon
DQO	data quality objective
DSR	Data Summary Report
DU	decision unit
dw	dry weight
EC_{10}	10 percent effect concentrations
Eco-SSL	ecological soil screening levels
ECSM	ecological conceptual site model
EDD	estimated daily dose
EPC	exposure point concentration
EPI	Estimation Programs Interface
EqP	equilibrium partitioning
ERA	ecological risk assessment
ERAGS	Ecological Risk Assessment Guidance for Superfund
ESB	Equilibrium Partitioning Sediment Benchmarks
ESBTU	equilibrium partitioning sediment benchmark toxic unit
ESV	ecological screening value
FCV	final chronic value

f_{oc}	fraction of organic carbon
FS	Feasibility Study
ft/ft	1 foot by 1 foot cross-sectional gradient of groundwater
ft^3/s	cubic feet per second
ft-amsl	feet above mean sea level
ft-bgs	feet below ground surface
GSD	geometric mean standard deviation
HCN	hydrogen cyanide
HHRA	Human Health Risk Assessment
HMW	high molecular weight
HQ	hazard quotient
HSD	Honest Significant Difference
IC_{10}	10 percent inhibition concentration
IC_{50}	50 percent inhibition concentration
IPaC	Information for Planning and Consultation
ISS	incremental soil sampling
ITRC	Interstate Technology and Regulatory Council
kg	kilogram
L	liter
LANL	Los Alamos National Laboratory
LC_{50}	lethal concentration in 50 percent of test organisms
LL	low level
LMW	low molecular weight
LOAEL	lowest observed adverse effects level
LOEC	lowest observed effect concentration
MATC	maximum acceptable toxicant concentration
MDEQ	Montana Department of Environmental Quality
MDL	method detection limit
mg	milligrams
mg/kg	milligrams per kilogram
mg/kg bw per day	milligrams per kilogram body weight per day
mg/L	milligrams per liter
mi^2	square miles
MPDES	Montana Pollutant Discharge Elimination System
NaCN	sodium-cyanide
NaF	sodium fluoride
NHD	National Hydrography Dataset
NOAA	National Oceanic and Atmospheric Agency
NOAEL	no observed adverse effects level
NOEC	no observed effect concentration
NRWQC	National Recommended Water Quality Criteria
ORNL	Oak Ridge National Laboratory
PAH	polycyclic aromatic hydrocarbons
PCB	polychlorinated biphenyl
PCDD	polychlorinated dibenzo-dioxin
PCDF	polychlorinated dibenzo-furan
RAIS	Risk Assessment Information System

RCRA	Resource Conservation and Recovery Act
RI	Remedial Investigation
RPD	relative percent difference
RSD	relative standard deviation
RSL	Regional Screening Levels
SAP	Sampling and Analysis Plan
SEDTOX	sediment toxicity
SEM	simultaneously extracted metals
SIM	selected ion monitoring
SLERA	Screening-Level Ecological Risk Assessment
SMDP	scientific management decision point
SOP	standard operating procedure
SPL	spent potliner
SQT	Sediment Quality Triad
SVOC	semi-volatile organic compound
SW	surface water
TAL	target analyte list
TCL	target compound list
TDS	total dissolved solids
TEC	Toxicity Equivalence Concentrations
TEF	toxicity equivalent factor
TEL	toxic effect level
TEQ	Toxicity Equivalency Quotient
TOC	total organic carbon
tPAH	total PAH
TRI	Toxics Release Inventory
TRV	toxicity reference value
TSS	total suspended solids
UCL	upper confidence limit
USEPA	United States Environmental Protection Agency
USFWS	United States Fish and Wildlife Service
USGS	United States Geological Survey
UST	underground storage tank
UV	ultraviolet
VOC	volatile organic compound
WAD	weak acid dissociable
WET	whole effluent toxicity
WHO	World Health Organization
WQB	water quality benchmark

1 Introduction

On behalf of Roux Environmental Engineering and Geology, D.P.C. (referred to herein as Roux) and Columbia Falls Aluminum Company, LLC (CFAC), EHS Support LLC (EHS Support) has prepared this Baseline Ecological Risk Assessment (BERA) as part of the ongoing Remedial Investigation/Feasibility Study (RI/FS) of the former CFAC aluminum reduction facility (commonly referred to as an aluminum smelter) Superfund Site located in Flathead County, Montana (Site). The RI/FS is being conducted pursuant to the Administrative Settlement Agreement and Order on Consent (AOC) dated November 30, 2015, between CFAC and the United States Environmental Protection Agency (USEPA) (Comprehensive Environmental Response, Compensation, and Liability Act [CERCLA] Docket No. 08-2016-0002).

As part of the RI/FS, a Site-wide ecological risk assessment (ERA) is being conducted in accordance with *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (ERAGS; USEPA, 1997). Per USEPA (1997) the functions of the ERA are to:

- Document whether actual or potential ecological risks exist at the Site;
- Identify which constituents present in exposure media at the Site pose an ecological risk; and
- Generate data to use in evaluating cleanup options

In addition to ERAGS, other relevant guidance documents that may be consulted to support the ERA process at the Site include, but may not be limited to, the following:

- *Determination of the Biologically Relevant Sampling Depth for Terrestrial and Aquatic Ecological Risk Assessments* (USEPA, 2015a)
- *Considerations for Developing Problem Formulations for Ecological Risk Assessments Conducted at Contaminated Sites Under CERCLA* (USEPA, 2004)
- *The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments* (USEPA, 2001a)
- *Guidance for the Data Quality Objective Process* (USEPA, 2000a)
- *Principles for Ecological Risk Assessment and Risk Management* (USEPA, 1999)
- *Guidelines for Ecological Risk Assessment* (USEPA, 1998)
- *Role of the Ecological Risk Assessment in the Baseline Risk Assessment* (USEPA, 1994)

ERAGS prescribes an eight-step process for the assessment of ecological risk to support risk management decision-making. The eight-step process includes several scientific management decision points (SMDPs) for the risk manager and risk assessment team to evaluate and approve or redirect the process (USEPA, 1997). The eight-step ERA process is conducted in a tiered-approach consisting of two phases of risk assessment:

- Screening-Level Ecological Risk Assessment (SLERA): The SLERA includes Steps 1 and 2 of the ERAGS process and represents a preliminary and conservative assessment of potential ecological risks to determine if additional steps in the ERAGS process are warranted.
- BERA: The BERA includes Steps 3 through 8 of the ERAGS process. A BERA is conducted to further characterize site-specific ecological risks and to support risk management and remedial decision-making for the protection of ecological receptors.

Roux prepared a SLERA (ERAGS Steps 1 and 2) for the Site based on data generated during the Phase I Site Characterization (Roux, 2017a). A Draft SLERA Report was submitted to the USEPA and Montana Department of Environmental Quality (MDEQ) on February 27, 2017, and comments on the Draft SLERA

Report were received from USEPA and MDEQ on April 14, 2017. A revised SLERA that incorporated USEPA and MDEQ comments was submitted on September 15, 2017 (Roux, 2017b). Based on conservative exposure assumptions, the SLERA identified constituents of potential ecological concern (COPECs) in surface water, sediment, or soil from exposure areas at the Site and concluded that there was insufficient information to dismiss potential ecological risk. The SLERA recommended further data gathering or analysis as part of a BERA to better understand ecological risk at the Site.

This BERA was conducted in accordance with final BERA Work Plan dated November 15, 2018 and approved by USEPA on November 30, 2018 (EHS Support, 2018).

Additionally, two interim deliverables describing major sub-components to the BERA Work Plan were submitted separately for review and approval by USEPA and MDEQ:

- *Technical Memorandum: Proposed Refined Ecological Screening Values (ESVs) to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site* (EHS Support, 2019a)
- *Technical Memorandum: Proposed Wildlife Exposure Modeling Approach to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site* (EHS Support, 2019b).

Comments were received and resolved on these interim deliverables prior to the completion of the BERA. The final technical memoranda are presented in **Appendix A1** and **Appendix A2**.

1.1 Purpose and Objectives

The overall purpose of the BERA is to evaluate whether environmental conditions associated with historical operations at the Site pose an unacceptable risk to ecological receptors based on the conceptual investigation framework presented in the BERA Work Plan. Specific objectives of this BERA include:

- Refine the screening-level problem formulation in the context of new information and findings of analyses conducted as part of the Phase I and Phase II Site Characterizations and the SLERA.
- Refine the ecological conceptual site model (ECSM) of the Site.
- Refine the list of COPECs identified in the SLERA to identify COPECs that are most likely to drive risk management decision-making for the Site to focus and streamline the BERA risk analysis.
- Develop screening-level and baseline ecological exposure estimates for complete exposure pathways identified in the refined ECSM for ecological exposure areas identified in the BERA Work Plan.
- Characterize risk based on baseline exposure estimates to support SMDPs for identified ecological exposure areas.
- Evaluate uncertainties in the exposure estimates and risk characterizations and the potential influence of uncertainties on risk conclusions.
- Identify potential data gaps based on the uncertainty analysis.

1.2 BERA Framework

The framework of this BERA is comprised of the following components:

- **Section 2** – Site Background, which consists of the Site and environmental settings.
- **Section 3** – Baseline Risk Assessment Problem Formulation, which includes descriptions of the nature and extent of contamination at the Site, summary of the SLERA, the ECSM, refinement of the COPECs, and assessment endpoints, risk questions, and measurement endpoints.

- **Section 4** – BERA Identification of COPECs, which includes the selection and identification of screening-level and refined COPEC lists based on the combined Phase I and Phase II Site Characterization datasets.
- **Section 5** – BERA Risk Analysis Plan, which includes key components of the effects analysis, exposure analysis, risk calculation, uncertainty analysis, and risk characterization that are investigated as part of the BERA.
- **Section 6** – Risk Characterization, which presents the results of the direct contact and wildlife ingestion evaluation of the refined COPECs.
- **Section 7** – Uncertainty Analysis, which discusses the areas of uncertainty in various components of the BERA that should be considered when interpreting the results and forming conclusions.
- **Section 8** – BERA Summary and Conclusions, which synthesizes the results of the risk characterization and uncertainty analysis to formulate a suggested strategy for further action, if warranted.
- **Section 9** – References, which lists the sources cited in this report.
- **Appendices** – Appendix files, which provide supporting information for the BERA, including:
  - Appendix A Interim Deliverables for the Baseline Ecological Risk Assessment Work Plan
  - Appendix B Screening-Level COPEC Identification Tables
  - Appendix C Calculated Dioxin Toxicity Equivalence Concentrations
  - Appendix D Calculated Ecological Screening Values for Hardness and pH Dependent Constituents
  - Appendix E Refined COPEC Identification Tables
  - Appendix F Equilibrium Partitioning Sediment Benchmark Calculations for Certain Non-ionic Organic Constituents
  - Appendix G Equilibrium Partitioning Sediment Benchmark Toxicity Units Calculations for Polycyclic Aromatic Hydrocarbons
  - Appendix H Food Chain Models for Calculating Doses to Representative Ecological Receptors
  - Appendix I ProUCL Output
  - Appendix J Incremental Soil Sampling Exposure Point Concentrations

2 Site Background

Pertinent background information for the CFAC Site is provided in this section. **Section 2.1** describes the Site setting, which includes information about the Site location and a summary of the operational history of the facility. **Section 2.2** details the environmental setting, which includes information about regional climatic conditions, localized hydrogeology, and aquatic, terrestrial, and transitional habitats identified at the Site.

2.1 Site Setting

The location and operational history of the CFAC Site is discussed in the **Sections 2.1.1** and **2.1.2**.

2.1.1 Site Location

The Site is located at 2000 Aluminum Drive in Columbia Falls, Montana (**Figure 2-1**). The Site is situated in the central portion of Flathead County, approximately 2 miles northeast of the City of Columbia Falls. The Site is accessed by Aluminum Drive via North Fork Road (County Road 486). The BERA study area consists of approximately 1,340 acres, which includes the former aluminum reduction facility and the surrounding area. The Site is generally bounded by the Cedar Creek Reservoir Overflow Ditch to the north and east, Teakettle Mountain to the east, Flathead River to the south, and Cedar Creek to the west (**Figure 2-2**).

2.1.2 Operational History

The Site was operated as a primary aluminum reduction facility (commonly referred to as an aluminum smelter) from 1955 until 2009. A detailed description of the operational history at the Site is provided in Section 2.7.2 of the RI/FS Work Plan (Roux, 2015a).

Buildings and industrial facilities remaining at the Site at the start of the Phase I Site Characterization included offices, warehouses, laboratories, mechanical shops, the Paste Plant, coal tar pitch tanks, pump houses, the Casting Garage, and the Potline Facility. The Site also includes seven closed landfills, one inactive landfill (not closed), material loading and unloading areas, two closed leachate ponds, and several wastewater percolation ponds. By January 2018, most structures on Site had been removed as part of ongoing decommissioning efforts. The structures that were removed include: West Rectifier, Rod Mill Building, Paste Plant, Quonset Hut, West Aluminum Unloader, Compressor Building, Laboratory, the Main Plant building (i.e., Pot Rooms 1 through 10), and the Change House. Several structures remain at the Site, including the administration building, the main warehouse, two ancillary warehouses, the fabrication shop, and five silos. **Figure 2-2** illustrates the locations of Site features pertinent to the BERA investigation.

2.2 Environmental Setting

The Site is situated within the Stillwater-Swan Wooded Valley ecoregion (Woods et al., 2002). Ecoregions denote areas of general similarity in ecosystems and in the type, quality, and quantity of environmental resources from a coarse (Level I) to a fine (Level IV) scale. The Stillwater-Swan Wooded Valley Level IV ecoregion is positioned west of the Canadian Rockies in the Northern Rockies area. The

valley floor sits at an elevation of approximately 3,300 feet above mean sea level (ft-amsl). This section includes descriptions of the regional climatic conditions, localized hydrogeology, and descriptions of the aquatic, terrestrial, and transitional habitats present at the Site.

2.2.1 Regional Climatic Conditions

The Site is located at a latitude of 48° 23' N. The elevation of the Site ranges from approximately 3,008 ft-amsl along the Flathead River to the south to 3,270 ft-amsl at the base of Teakettle Mountain to the east. Its mid-hemisphere latitude and intermontane setting results in wide seasonal climatic swings. Average annual precipitation in the region ranges from about 14 inches to 25 inches depending on the year. Greater precipitation at higher elevations is common; much of the precipitation is stored as snow. The regional climate is considered modified maritime (i.e., much of the precipitation regime is influenced by moist air masses from the Pacific Ocean traveling from west to east). Dry, cold air masses often move in the north to south direction from Canada. The mean annual temperature for nearby Kalispell, Montana is 43.25 degrees Fahrenheit (6.25 degrees Celsius).

2.2.2 Localized Hydrogeology

The following sections describes the regional and Site-specific features that influence surface water and groundwater flow in the region and the Site.

2.2.2.1 Surface Water Hydrology and Watershed Characteristics

The Site is located within the Flathead River watershed. As discussed above, the Site is bordered by surface water features of varying hydrology on each side, including the Flathead River to the south, Cedar Creek to the west, and intermittent Cedar Creek Reservoir Overflow Ditch to the north and east (**Figure 2-2**).

The Flathead River is a tributary to the Columbia River, which flows into the Pacific Ocean. The North Fork of the Flathead River originates in the province of British Columbia, Canada. The Middle Fork of the Flathead River originates in the Bob Marshall Wilderness located south of Glacier National Park. The confluence of the North Fork and Middle Fork of the Flathead River is approximately 10 miles upstream of the Site, north of Coram, Montana. The South Fork joins the main stem of the Flathead River at the entrance of Badrock Canyon located approximately 2 miles upstream of the Site. The Flathead River flows west through Badrock Canyon towards the City of Columbia Falls where its course is then southerly toward Flathead Lake. At the Site, the drainage area of the Flathead River is approximately 4,470 square miles (mi^2), which includes the drainage area of Cedar Creek to the west.

The United States Geological Survey (USGS) maintains three gauging stations on the Flathead River in the general vicinity of the Site. The closest station is located approximately 3 miles southwest of the Site near Columbia Falls (USGS Station #12363000). Two stations are located approximately 10 miles north-northeast of the Site, i.e., the north fork station on the Flathead River and the middle fork station immediately west of Glacier National Park (USGS Stations #12355500 and #12358500, respectively). For the October 1951 to September 2016 period of record at the Columbia Falls USGS station, , the mean monthly discharge was lowest in August across that time frame with an average flow rate of 5,340 cubic feet per second (ft^3/s). Mean monthly discharge was greatest in June across that time frame with an average flow rate of 24,900 ft^3/s. The increased discharge in June corresponds to the period when

average precipitation in the region is greatest. Meltwater from high elevation snowpack also contributes to the increased discharge in May and June (EHS Support, 2018). Variability in the flow rates of the Flathead River are discussed in more detail in the Phase II Data Summary Report (DSR) (Roux, 2019).

Cedar Creek originates north of the Site in the area contributing to the Cedar Creek Reservoir. At the outlet of the Cedar Creek Reservoir, the upgradient catchment area is 12.5 mi^2. From the reservoir outlet, Cedar Creek flows approximately 3 miles southwest towards the City of Columbia Falls. The elevation of Cedar Creek is higher than groundwater elevations within the Site, indicating that Cedar Creek is a losing stream rather than a gaining stream. According to the USGS National Hydrography Dataset (NHD), a tributary to Cedar Creek is mapped that bisects the northern area of the Site. This intermittent feature is shown to be situated along the eastern side of the Industrial Landfill and joins Cedar Creek approximately 0.5 mile to the southwest of the Industrial Landfill. This feature was not observed during Site investigation activities; however, surface water ponding and wetland vegetation were observed in the area south and southeast of the Industrial Landfill. Based on field observations, the source of the ponding was attributed to seeps in the nearby cliff. This feature was generally mapped by Roux field personnel and is identified on **Figure 2-2** as the Northern Surface Water Feature. At the western Site boundary, Cedar Creek drains an additional 1.5 mi^2, predominately from the western two-thirds of the Site.

The Cedar Creek Reservoir Overflow Ditch flows intermittently in the spring and regulates flow for Cedar Creek and the Cedar Creek Reservoir (Hydrometrics, 1985). Based upon proximity and land surface topography, some surface water runoff from the eastern side of the Site, originating from the East Landfill and the Sanitary Landfill, as well as runoff from the western flank of Teakettle Mountain, flows to the Cedar Creek Reservoir Overflow (**Figure 2-2**). Excluding potential upgradient contributions from the Cedar Creek Reservoir, the Cedar Creek Reservoir Overflow has a catchment area of approximately 2.0 mi^2. About 20 percent of this catchment area originates on-site and the remaining catchment extends to the peak of Teakettle Mountain to the east. Like Cedar Creek, the elevation of Cedar Creek Reservoir Overflow is higher than surrounding groundwater elevations within the Site, indicating that the Cedar Creek Reservoir Overflow drainage is a losing stream.

2.2.2.2 Site Hydrogeological Units

The stratigraphic units underlying the Site form a complex hydrogeologic framework that influences groundwater elevations, groundwater flow, and the migration of constituents of potential concern (COPCs) beneath the Site. Three major stratigraphic units were identified during the Phase I Site Characterization and are described in the *Phase I Site Characterization Data Summary Report* (Phase I DSR; Roux, 2017a). The three stratigraphic units consist primarily, from land surface down, of:

- Layer of glaciofluvial and alluvial coarse-grained soils, varying in vertical extent and grain size depending on the vicinity to the Site features (i.e., Teakettle Mountain, Flathead River)
- Layer of dense, poorly-sorted glacial till with interbedded deposits of glaciolacustrine clays and silts
- Bedrock

The coarse-grained glacial outwash and alluvium deposits that are found above the glacial till are collectively referred to as the “upper hydrogeologic unit” at the Site (Roux, 2017c). The coarse-grained glacial deposits that comprise the upper hydrogeologic unit account for the main water bearing unit beneath the Site. The glacial tills found below the upper hydrogeologic unit were typically characterized

as containing a higher percentage of fines that were denser and drier than the overlying outwash and alluvium deposits. The till deposits were often characterized as stiff and moist or dry. These observations indicate that the till deposits likely have a lower hydraulic conductivity than the overlying outwash and alluvium deposits in the upper hydrogeologic unit. The bedrock beneath the till has metamorphosed over time, resulting in a tightly compacted, low porosity and low permeability unit. Based upon the conceptual site model, bedrock is considered to define the bottom of the hydrogeologic system beneath the Site.

2.2.2.3 Groundwater Occurrence and Flow

Groundwater flow in the region tends to follow surface topography (USEPA, 2011). Groundwater is typically recharged from direct infiltration and surface water sources, which include reservoirs, ponds, streams, and lakes (LaFave et al., 2004). Groundwater in the region may also discharge to surface water bodies, depending on the season and localized conditions.

Groundwater occurrence and movement was evaluated during the Phase I Site Characterization described in the Phase I DSR (Roux, 2017a) and the *Groundwater and Surface Water Data Summary Report* (Roux, 2017c), and during the Phase II Site Characterization described in the Phase II DSR (Roux, 2019). During the Phase I Site Characterization, 64 monitoring wells were visited on the following dates to measure depth to groundwater across the Site: August 30, 2016; November 29, 2016; March 14-15, 2017; and June 16, 2017. During the Phase II Site Characterization, 77 monitoring wells (including 8 newly installed monitoring wells and 5 former production wells) were visited on June 4-5, 2018 and October 1-2, 2018, to measure depth to groundwater across the Site. Pressure transducers were also installed in selected wells to monitor groundwater elevations throughout the Phase I and Phase II Site Characterization. The elevation data collected from gauging and from the pressure transducers indicate that groundwater elevations fluctuate seasonally at varying magnitudes depending on the area of the Site, and the hydrogeologic unit where the well is screened. Additionally, groundwater elevations measured in monitoring well clusters, where there is a well screened within the upper hydrogeologic unit and an adjacent deep well screened below the upper hydrogeologic unit, indicates a downward vertical gradient exists. However, the differences in elevations between the glacial till and the upper hydrogeologic unit is typically greater than 25 feet, and in some cases exceeds 50 feet. This large difference is indicative of limited (if any) hydraulic connectivity between the two water bearing zones.

Groundwater flow across the Site in the upper hydrogeologic unit is generally in the south-southwest direction towards the Flathead River. While the southerly flow direction is consistent across the Site, the discussion of the hydraulic gradient can be divided into three distinct areas:

- Near Teakettle Mountain and in the landfill area of the Site, the groundwater hydraulic gradient is steep (approximately 0.059 ft/ft [1 foot by 1 foot cross-sectional gradient of groundwater, ft/ft]) and generally mirrors the steeper topography in that portion of the Site.
- Groundwater elevations in the center of the Site (near the North Percolation Ponds, former Operational Area, and northern half of the Main Plant Area) are consistent over long distances (typically within 1 foot over distances greater than 1,000 feet), indicating a relatively flat groundwater hydraulic gradient (approximately 0.0045 ft/ft) across the center of the Site.
- The gradient then increases in the southern area of the Site between the Main Plant Area and the Flathead River (approximately 0.031 ft/ft), which is also consistent with the steep drop in topography between the railroad and the Flathead River.

The gradients above and the elevations measured in the Flathead River generally indicate that the groundwater in the upper hydrogeologic unit appears to discharge to the Flathead River.

2.2.3 Description of Aquatic, Terrestrial, and Transitional Habitats

Aquatic, terrestrial, and transitional habitats are present within the Site. This section describes the general physical, hydrological, or vegetative characteristics of habitats within the Stillwater Swan Wooded Valley ecoregion where the Site is located in Montana (Woods et al., 2002). The habitat types described for the Site are used as the basis for identifying ecological exposure areas for the BERA (**Section 3.3.1**).

Aquatic habitats are characterized by perennial or near-perennial inundation with water and physical habitats that can support aquatic receptor species. In lotic aquatic habitats (flowing streams and rivers), flow conditions are suitable for the establishment of fish and invertebrate communities, as well as semi-aquatic birds or mammals that rely on aquatic flora or fauna as a food resource. Two lotic aquatic habitats exist within and around the Site, including the Flathead River and Cedar Creek. The Flathead River is considered a large river by the MDEQ. Large rivers are non-wadeable and almost always seventh-order or higher according to the Strahler stream order index (Strahler, 1964). Key physical habitat features of the Flathead River include cobble or gravel substrate; deep, fast-flowing water; and, depending on valley dimensions, multi-thread channels. In the river reach adjacent to the Site, the Flathead River provides marginal fish habitat for common species, with this section of the river being used as a migration corridor to access areas of more suitable habitat (Stagliano, 2015). Given the absence of extensive agriculture or other non-anthropogenic nutrient sources upgradient, the Flathead River is considered oligotrophic, which means that it lacks macronutrients, such as phosphorus.

Cedar Creek is a small headwater stream that discharges to the Flathead River. Small headwater stream habitats in the region can be distinguished primarily by their hydrologic regime. Montane headwater streams that originate in the high-elevation peaks have characteristically high spring and early summer flows, with the spring freshet due to snow melt. Small headwater systems are also often oligotrophic.

Terrestrial habitats are dry, upland areas that may support aboveground and/or belowground terrestrial flora and fauna. Soils that are considered terrestrial habitat are limited to the vadose, or unsaturated, zone of the soil profile. Vegetation type is another key characteristic of physical terrestrial habitats. There are four primary terrestrial habitats on the Site, which are characterized predominately by the type of vegetation present. These habitats include mixed conifer forest, riparian forest, deciduous shrubland, and open grassland. Detailed descriptions of each terrestrial habitat type and associated flora and fauna are provided in the SLERA (Roux, 2017b).

Transitional habitats are characterized by intermittent or seasonal surface water inundation. Transitional habitats can potentially support aquatic receptor species during certain life stages (e.g., benthic invertebrates, juvenile herpetofauna), as well as terrestrial species during dry periods (e.g., soil invertebrates, terrestrial plants).

Ecological exposure areas identified based on on-site habitat types are defined in **Section 3.3.1**. The evaluation of potential ecological receptors within exposure areas is distinguished based on the presence of aquatic, terrestrial, or transitional habitat characteristics.

3 Baseline Risk Assessment Problem Formulation

The purpose of the baseline problem formulation is to re-evaluate the screening-level problem formulation in the context of new information and findings of analyses conducted as part of the ongoing investigation at the Site. The baseline problem formulation establishes risk assessment goals, characterizes ecological effects of primary COPECs, and updates the preliminary ECSM. The refined ECSM is used to define assessment endpoints, risk questions, and measurement endpoints to guide the development of the conceptual BERA study design. The following sections present the preliminary baseline problem formulation that was previously presented in the SLERA (Roux , 2017b) and Phase I Site Characterization (Roux, 2017a). Any additions or modifications of the preliminary baseline problem formulation based on the review of the Phase II data are incorporated in the individual components of the problem formulation described below.

3.1 Nature and Extent of Contamination

In 2013, Weston Solutions, Inc. (Weston) completed an investigation at the Site on behalf of USEPA Region 8. The results were summarized in the April 2014 report titled *Site Reassessment for Columbia Falls Aluminum Company Aluminum Smelter Facility, Columbia Falls, Flathead County, Montana prepared for United States Environmental Protection Agency Region 8* (Weston, 2014). As part of the investigation, a total of 68 groundwater, surface water, sediment, and soil samples were collected at the Site. Results were used by the USEPA to establish if an observed release had occurred at the Site as that term is defined in the USEPA Hazardous Ranking System Guidance Manual. The data collected during the Weston investigation was considered when developing the Scope of Work for the Phase I Site Characterization that was completed by Roux, on behalf of CFAC, in 2016 and 2017.

The Phase I Site Characterization program was designed to identify and/or confirm source areas and broadly characterize the nature and extent of associated constituents of concern across the Site and around Site features. Based on the preliminary conceptual site model (CSM) presented in the RI/FS Work Plan, the nature and extent of contamination was evaluated from the following site features identified as potential source areas (**Figure 2-2**):

- Landfills (including the closed Wet Scrubber Sludge Pond and the closed leachate ponds)
- Former Drum Storage Area
- Percolation ponds
- Waste and raw materials storage and handling areas
- Plant drainage system including drywells and associated discharge points
- Underground storage tanks (USTs) and aboveground storage tanks (ASTs)

The results of the Phase I Site Characterization indicated that cyanide, fluoride, and polycyclic aromatic hydrocarbons (PAHs) are the primary COPCs identified within the potential source areas and Site features (Roux, 2017a). A summary of key findings regarding the nature and extent of constituents as it relates to the baseline problem formulation include:

- Elevated[1] cyanide and fluoride concentrations in groundwater within the upper hydrogeologic unit appear to originate immediately to the west of the Wet Scrubber Sludge Pond, with maximum concentrations immediately downgradient of the West Landfill and Wet Scrubber

[1] The term “elevated” refers to concentrations that are considered to be high relative to a benchmark value, background statistic, etc.

Sludge Pond. The Center Landfill also appears to be a source of cyanide and fluoride in groundwater. Cyanide and fluoride concentrations in groundwater to the east and northeast of these site features, and downgradient of other site landfills, are generally orders of magnitude lower.

- Soils adjacent to the West Landfill contained elevated concentrations of cyanide, fluoride, and PAHs.
- Elevated cyanide and fluoride concentrations were observed in soil and groundwater in the Former Drum Storage Area, located immediately to the west of the Wet Scrubber Sludge Pond and West Landfill.
- Concentrations of PAHs and cyanide in the percolation ponds were typically greatest in soil and sediment in the North-East Percolation Pond and its influent ditch, followed by the effluent ditch, North-West Percolation Pond, and West Percolation Pond; concentrations of COPCs decreased with increasing depth in the percolation ponds.
- COPCs detected in soil and sediment in the South Percolation Ponds were similar to the other percolation ponds, but concentrations were generally much lower than the other ponds.
- Cyanide, fluoride, and PAHs were the primary COPCs detected in soils throughout the Main Plant Area.
- Low level detections of benzene, toluene, ethylbenzene, and xylene (BTEX) were the primary volatile organic compounds (VOCs) in soils across the Site. The presence of BTEX may be related to petroleum coke and pitch materials used at the Site.
- The Phase I Site Characterization found that naturally-occurring metals were detected in soil and sediment samples across the Site. A comprehensive evaluation of Phase I and Phase II concentrations in Site data compared to background concentrations was performed in the DSR Report (Roux, 2019) and within this BERA as part of the COPEC refinement step (please see Sections 3.6.4 and 4.4.2 for additional details). This analysis was used to identify which metals (and some organic constituents with widespread anthropogenic sources) are consistent with background concentrations, as compared to constituents that may be present as a result of site operations.
- Pesticides were not detected in any soil samples collected during the Phase I Site Characterization; however, mean and median method detection limits (MDLs) for some pesticides exceeded the lowest screening criteria.
- Polychlorinated biphenyls (PCBs) were not detected in discrete samples in the site-wide soil dataset; however, PCBs were detected in four decision units (DUs) within the central portion of the Operation Area.
- Consistent with the preliminary CSM, soil and groundwater results from the Phase I Site Characterization indicate low potential for soil vapor exposure based on low VOC concentrations detected in soil and groundwater.

The findings from the Phase II Site Characterization sampling effort (Roux, 2019) were generally similar to the Phase I Site Characterization (Roux, 2017a):

- Cyanide, fluoride, and PAHs are primary COPCs in soil at the Site. The Site-wide soil quality observed during the Phase II Site Characterization is consistent with the findings of the Phase I Site Characterization. The highest concentrations of these COPCs in soil were generally found in the industrial areas of the Site including the Main Plant and Operational Area, the North Percolation Ponds, and the Central Landfill Area.
- The results of the background sampling from the Phase II Site Characterization and statistical data analysis indicate that many of the metal concentrations observed in soil samples are likely

a result of metals present at background concentrations. However, some of the areal distribution of metal detections and the magnitude of metal concentrations around certain Site features may also be a result of the former Site operations.

- Dioxin and furan compounds were detected in all soil samples collected during the Phase I Site Characterization and Phase II Site Characterization. Concentrations were highest within or adjacent to the Rectifier Yards (immediately south and northeast) but not at locations within the remainder of Main Plant Area or in the Western Undeveloped Area. Low concentrations of dioxin and furan compounds are wide-spread and are present at similar concentrations in the Western Undeveloped Area and the background reference locations.
- PCBs were detected in some soil samples, primarily in locations just south of the Wet Scrubber Sludge Pond; however, PCBs are not widespread in Site-wide soils.
- VOCs were frequently detected in soil samples across the Site. The widespread distribution of petroleum VOCs across the Site is somewhat similar to that of PAHs. The frequent detection of petroleum-related VOCs at trace levels in soil is likely attributed to the presence of these VOCs, albeit at low concentrations, in the petroleum coke and pitch materials that were used in manufacturing at the Site and were the primary sources of PAHs at the Site.
- Concentrations of cyanide and fluoride measured in Backwater Seep Sampling Area and the South Percolation Ponds were consistent with the suspected areas where groundwater is expressed from the upper hydrogeologic unit.
- Surface water sampling confirmed that many naturally occurring metals were detected frequently in surface water samples. Concentrations exceeding screening values were most commonly observed in the North and South Percolation Ponds and Flathead Riparian Area Channel.
- Semi-volatile organic compounds (SVOCs) (primarily PAHs) were detected in surface water samples, but not were not observed at elevated concentrations.
- Cyanide, fluoride, and PAHs in sediment samples were detected most frequently in the Backwater Seep Sampling Area, Flathead Riparian Area Channel, and North and South Percolation Ponds. Cyanide concentrations exceeded the USEPA Residential regional screening level (RSL) in five sediment samples, including sediment samples within and west of the Backwater Seep Sampling Area, the western most South Percolation Pond, and the North-East Percolation Pond. PAHs were most frequently detected in the North Percolation Ponds, the Backwater Seep Sampling Area, and the South Percolation Ponds.
- Similar to site-wide sediment and surface water quality data, cyanide and fluoride were detected most frequently and at the highest concentrations in sediment pore water samples in the Backwater Seep Sampling Area, Flathead Riparian Area Channel, and South Percolation Ponds. Cyanide concentrations in pore water which exceeded the DEQ-7 Acute Aquatic Life Standard occurred in the Backwater Seep Sampling Area, Flathead Riparian Area Channel, and the South Percolation Ponds. Fourteen different dissolved metals were detected in sediment pore water during the Site Characterization.
- The comparison of background and site surface water analytical data indicated that total cyanide, free cyanide, fluoride, select total and dissolved metals, and select PAHs in surface water are potentially Site-related within most or all (depending on the analyte and feature) of the surface water features.

3.2 Summary of Screening-Level Ecological Risk Assessment

The initial SLERA that was performed using the results of the Phase I Site Characterization (Roux, 2017a) provided a preliminary assessment of potential risks to ecological receptors that may be exposed to Site constituents in soil, surface water, and sediment (Roux, 2017b). It should be noted that all steps of the initial SLERA were revisited in this BERA following the collection and analysis of the Phase II data (**Section 4**). The SLERA problem formulation included a preliminary ECSM that was developed for aquatic and terrestrial exposure areas. The preliminary ECSM described potential sources of constituents, release mechanisms, exposure media, representative receptor groups, and the complete exposure pathways for each receptor/medium combination.

Based on the review of the historical processes and data collected during the SLERA, COPECs were identified in surface water, sediment, and surface soil to which ecological receptors could potentially be exposed (Roux, 2017b). COPECs were identified in the exposure analysis presented in the SLERA, which assumed maximum exposure scenarios based on comparisons of maximum exposure point concentrations to the most conservative ecological screening values (ESVs) (i.e., the minimum ESV) from a list of screening criteria sources developed in discussions with USEPA. The conservative assumptions of the SLERA exposure analysis could not be used to conclude that unacceptable risk does not exist. Rather, the findings of the exposure analysis indicated that certain COPECs and associated exposure pathways require further evaluation.

Based on these results, the SLERA concluded that there was a potential for adverse ecological effects and a more thorough assessment was warranted (USEPA, 1997). Given the uncertainties in the exposure analysis described above, it was recommended that the ecological risk assessment process proceed to ERAGS Step 3 (Baseline Risk Assessment Problem Formulation). The following section presents a refined ECSM based on the SLERA and additional information developed since the submittal of the SLERA.

3.3 Ecological Conceptual Site Model

Based on the findings of the SLERA (Roux, 2017b) and Phase I and II Site Characterizations (Roux, 2017a and 2019, respectively), the preliminary ECSM developed in the SLERA was refined to incorporate new information fundamental to the design of additional data collection activities to support the BERA. Key elements of the preliminary ECSM that were refined in the BERA problem formulation include:

- Exposure areas: Ecological exposure areas were re-defined based on the outcome of the SLERA to represent the habitat types (aquatic, transitional, and terrestrial) and receptor groups that may be present and exposed to site constituents.
- Ecological receptor categories: Additional ecological receptor categories and representative receptor species, including updated queries of special status species (e.g., rare, threatened, and endangered species), were identified in the refined ECSM.
- Exposure pathways: Potential exposure pathways were re-evaluated based on the SLERA findings to assess fate and transport properties of COPECs that may influence mobility and/or exposure routes to receptor categories.
- Bioavailability: The refined ECSM includes an evaluation of the site characteristics that may influence the bioavailability of primary COPECs in site exposure media.
- Bioaccumulation/biomagnification: The relative importance of COPECs that bioaccumulate or biomagnify were evaluated in the refined ECSM to identify potential data gaps that may be addressed in the BERA.

The following sections present the refined ECSM for the BERA problem formulation.

3.3.1 Ecological Exposure Areas

Ecological exposure areas presented in the SLERA were refined to represent primary habitat types and receptor groups that may be exposed to site constituents. Ecological exposure areas were grouped into three broad categories based on habitat types:

- Terrestrial Exposure Areas
- Transitional Exposure Areas
- Aquatic Exposure Areas

The following sections describe the categories of ecological exposure areas identified for the BERA problem formulation. The spatial extents of ecological exposure areas are illustrated in **Figure 3-1**.

3.3.1.1 Terrestrial Exposure Areas

Terrestrial exposure areas consist of upland habitats and include the following (**Figure 3-1**):

- Main Plant Area (231.9 acres)
- Central Landfills Area (91.4 acres)
- Industrial Landfill Area (12.6 acres)
- Eastern Undeveloped Area (32.1 acres)
- North-Central Undeveloped Area (114.4 acres)
- Western Undeveloped Area (439.6 acres)
- Flathead River Riparian Area (93.9 acres)

The primary habitat types within the terrestrial exposure areas include mixed conifer forest, riparian forest, deciduous shrubland, and open grassland. Conifer forests are predominantly found to the north and west of the Main Plant Area and are mostly bordered by riparian woodlands. Several areas of deciduous shrubland are located northeast and east of the Main Plant Area. Open grasslands are located immediately north and west of the Main Plant Area, between the Main Plant Area and the mixed conifer and riparian forests.

Site-related constituents from features identified as potential source areas may be present in environmental media, specifically soil, in the terrestrial exposure areas. Current primary constituent migration pathways from potential source areas to terrestrial exposure areas may include overland stormwater runoff associated with precipitation or snowmelt events. Historically, atmospheric deposition was also a potential constituent migration pathway from site emission sources. Habitats within the terrestrial exposure areas may support multiple receptor groups, including terrestrial plants, soil invertebrates, herptiles, birds, and mammals. Terrestrial exposure areas do not provide aquatic or transitional habitats, and therefore, do not support aquatic receptors. Receptors may use the terrestrial exposure areas for foraging and reproduction. The ecological relevance of these habitats may vary among the terrestrial exposure areas based on the degree of historical site operations and infrastructure, such as buildings and impervious surfaces. For example, developed areas within the Main Plant Area and Central Landfills Area provide limited habitat value for terrestrial receptors under current exposure conditions due to disturbances related to site activities.

3.3.1.2 Transitional Exposure Areas

Transitional exposure areas consist of intermittently- or seasonally-wetted habitats and include the following (**Figure 3-1**):

- North Percolation Pond Area (11.3 acres)
- South Percolation Pond Area (5.6 acres)
- Cedar Creek Reservoir Overflow Ditch (5.2 acres)
- Northern Surface Water Feature (6.1 acres)

Site-related constituents from features identified as potential source areas may be present in environmental media, including soil, surface water, sediment, and pore water in the transitional exposure areas. Primary constituent migration pathways from potential source areas to the transitional exposure areas may include overland stormwater runoff associated with precipitation or snowmelt events and direct discharges of stormwater and formerly wastewater (e.g., North and South Percolation Pond Areas). Habitats provided by transitional exposure areas range from aquatic to terrestrial depending on seasonal climatic and hydrogeologic conditions and may also range in quality depending on historical site operations. For instance, the North Percolation Ponds were constructed for wastewater management and were not designed to provide wildlife habitat. Therefore, the North Percolation Ponds may support lesser numbers of the aquatic and terrestrial receptor groups identified in **Section 3.3.5**due to the marginal habitat conditions available. Based on the intermittent nature of aquatic habitats in these transitional exposure areas, it is unlikely that permanent aquatic communities would be established. These areas may be important for the reproduction of amphibians and may also provide drinking water sources for terrestrial receptors during wet periods of the year.

3.3.1.3 Aquatic Exposure Areas

Aquatic exposure areas consist of perennially-wetted habitats and include the Flathead River Area and Cedar Creek Area (**Figure 3-1**). These exposure areas are located on the borders of the Site to the south and northwest, respectively. Site-related constituents from features identified as potential source areas may be present in environmental media, including surface water, sediment, and pore water in the aquatic exposure areas. Primary constituent migration pathways from potential source areas to the aquatic exposure areas may include groundwater discharge to surface water and overland stormwater runoff associated with precipitation or snowmelt events. Habitats within the aquatic exposure areas may support multiple aquatic receptor groups, including aquatic plants, benthic invertebrates, fish, herptiles, and semi-aquatic birds and mammals. These receptor groups may use the aquatic exposure areas for foraging and reproduction. In addition to aquatic receptors, aquatic exposure areas may also provide drinking water sources for terrestrial receptors, such as herptiles, birds, and mammals.

3.3.2 Source Areas

Based on the preliminary CSM presented in the RI/FS Work Plan (Roux, 2015a) and updated in the Phase I and Phase II DSRs, the nature and extent of contamination was evaluated from the following site features that were identified as potential source areas:

- Landfills (including the closed Wet Scrubber Sludge Pond and the closed leachate ponds)
- Former Drum Storage Area
- Percolation ponds
- Waste and raw materials storage and handling areas

- Plant drainage system including drywells and associated discharge points
- USTs and ASTs

The potential source areas associated with each ecological exposure area were identified in the refined ECSM, as presented in **Figure 3-2** for terrestrial exposure areas, **Figure 3-3** for transitional exposure areas, and **Figure 3-4** for aquatic exposure areas.

3.3.3 Fate and Transport Pathways

The fate and transport of site-related constituents released into the environment depends on the physicochemical properties of the constituent and environmental media, and the physical characteristics of the migration pathway. Constituents may partition in various environmental media, such as surface water, sediment, and soil, which affects the potential ecological risks posed to aquatic and terrestrial receptors. The primary constituent migration pathways, from the site features identified as potential source areas presented in **Section 3.3.2** to the ecological exposure areas described in **Section 3.3.1,** may include groundwater discharge to surface water, overland stormwater runoff associated with precipitation or snowmelt events, direct discharges of stormwater and formerly wastewater, and historically, atmospheric deposition from site emission sources.

Groundwater discharge to surface water occurs in the Flathead River. Groundwater from the upper hydrogeologic unit beneath the Site is not known to discharge to surface water in any other aquatic or transitional exposure areas. Groundwater elevations are lower than the elevations of Cedar Creek and the Cedar Creek Reservoir Overflow Ditch; therefore, these systems are considered to be losing systems with surface water recharging groundwater. The Northern Surface Water Feature is an intermittent feature that appears to be fed by seeps located to the north and west. Snowmelt and increased seasonal precipitation create an elevated water table, which feeds these seeps in the Northern Surface Water Feature in the spring.

Shallow groundwater from the upper hydrogeologic unit beneath the Site discharges to the Flathead River. A groundwater seep has been identified along the Flathead River in the Backwater Seep Sampling Area of the Site (**Figure 2-2**). Cyanide and fluoride are the primary constituents of concern identified in the groundwater seep. The discharge of cyanide and fluoride in groundwater to the Flathead River adjacent to the Site has been authorized by Montana Pollutant Discharge Elimination System (MPDES) permit number MT-0030066 since first issued in May 1994, and subsequently renewed in 1999 and July 2014. On January 24, 2019, MDEQ provided a Notice of Intent to terminate the permit. In the Statement of Basis that accompanied the 1999 MPDES Permit No. MT-00330066, MDEQ noted the following (MDEQ):

- Cyanide is not persistent in surface water due to photo-degradation and volatilization
- The mixing zones provided for in the permit would have no effect on fish migration in the Flathead River
- There are no spawning or nursery areas, no effects to fish migration, and no evidence of attraction to the cyanide concentration in the acute mixing zone backwater channel, and;
- There was no anticipated impact on aquatic species or other species.

Constituents in groundwater discharged to surface water may remain in dissolved form, adsorb to suspended particulates, or partition to fine-grained sediments within the receiving exposure areas. Cyanide and metal-cyanide anions, as well as dissolved metals, may adsorb to oxide minerals or clays

with high anion exchange capacities, which may influence their bioavailability and potential ecological risks posed to ecological receptors.

Overland stormwater runoff associated with precipitation or snowmelt events is another potential constituent migration pathway from site features identified as potential source areas to ecological exposure areas. Stormwater may transport constituents in dissolved form or adsorbed to suspended sediment or soil particles. Dissolved forms are subject to the processes described above, while constituents adsorbed to soil or sediment particles being transported by stormwater will eventually settle in depositional areas of the given ecological exposure area, whether aquatic, transitional, or terrestrial. The age of constituents within soils also affects the fate and transport processes described above. The likelihood of dissolved-phase transport and bioavailability often decreases with increased time since the constituent entered the soil. Smolders et al. (2009) evaluated 10 percent inhibition endpoints for plants, soil invertebrates, and microbial processes exposed to metals in aged versus freshly contaminated soils. The findings of the evaluation indicated that total soil metal concentrations resulting in 10 percent inhibition endpoints in freshly amended soils were up to 100-fold lower than total soil metal concentrations resulting in 10 percent inhibition in aged or field-contaminated soils (Smolders et al., 2009).

Several transitional exposure areas received direct wastewater and stormwater discharges from historical Site operations, including the North Percolation Pond Area and South Percolation Pond Area. Although wastewater is no longer discharged to these exposure areas, the site stormwater conveyance system still discharges to these exposure areas. Stormwater may transport site-related constituents, including aluminum, cyanide, and fluoride, as previously described.

3.3.4 Exposure Media and Exposure Pathways

The Phase I and Phase II Site Characterization Data Summary Reports indicated that site-related constituents are present in environmental media at the Site (Roux, 2017a and 2019). The type(s) of impacted environmental media varies among the different ecological exposure areas and associated habitats, and may include surface water, sediment (including pore water), and soil. Ecological receptor exposure pathways to constituents within the impacted environmental media include ingestion (direct and incidental), and to a lesser extent (based on the COPECs identified), direct contact and inhalation. The exposure media and pathways identified in the refined ECSM are presented in **Figure 3-2** for terrestrial exposure areas, **Figure 3-3** for transitional exposure areas, and **Figure 3-4** for aquatic exposure areas.

3.3.4.1 Direct Contact

Direct contact is considered a complete exposure pathway for select aquatic and terrestrial receptors (including plants, invertebrates, fish, and amphibians) that may be exposed to constituents in sediment and surface water through direct contact via absorption through plant tissue, gills, or skin. Select terrestrial receptors (including plants and soil invertebrates) may be exposed to constituents in surficial soil through direct contact via absorption through plant tissue or skin. Other semi-aquatic and terrestrial receptors may be exposed to constituents in surface water, sediment, or soil through direct contact; however, this exposure pathway is considered secondary to ingestion pathways for these receptors. Dermal contact exposure pathways to birds and mammals are not considered significant exposure pathways due to the presence of fur on mammals, feathers on birds, and scales on reptiles that mitigate

direct dermal exposure (USEPA, 2005b). Therefore, the direct contact exposure pathway was only evaluated quantitatively for plants, invertebrates, fish, and amphibians (**Figures 3-2** through **3-4**).

3.3.4.2 Ingestion – Direct and Indirect

Ingestion of impacted environmental media, including direct ingestion of dietary items and surface water and indirect ingestion of sediment and soil, is the primary exposure pathway of concern for most upper trophic aquatic and terrestrial receptors. Direct ingestion of dietary items may be an important exposure pathway if environmental media are impacted by persistent, bioaccumulative constituents. Persistent, bioaccumulative constituents in sediment, surface water, and soil may be assimilated by lower trophic level species, bioaccumulated in tissues, and transferred to higher trophic level species that consume lower trophic level species.

Exposure through ingestion pathways varies based on the foraging habits and ranges of the receptor. For instance, some receptors have small home ranges and forage within a localized area for their entire lifetime, while others, such as migratory receptors, may only forage in a specific area for a brief period before leaving to forage elsewhere. Incidental ingestion of impacted environmental media, such as soil or sediment, while grooming or foraging may also occur, but is considered secondary to the direct ingestion pathway.

3.3.4.3 Inhalation

Inhalation is a potentially complete, but secondary exposure pathway for terrestrial receptors. This exposure pathway may include the inhalation of constituents that have volatilized, or that are adsorbed to airborne particulates. Burrowing animals may be exposed to constituents through inhalation pathways while occupying burrows. Inhalation exposure pathways may be related to the inhalation of VOCs in soil vapor or soil dust particles within the burrow. Based on the SLERA and other Phase I Site Characterization data, VOCs were infrequently detected and not identified as COPCs in soils from terrestrial exposure areas where burrowing mammals may be present. Therefore, it is not likely that exposure to VOCs in subsurface soil vapor contributes significantly to the risk to potential burrowing animals at the Site. Burrowing animals may also be exposed to constituents sorbed to respirable dust particles that may be inhaled while occupying burrows. However, the inhalation of respirable dust is likely to have a minor contribution to overall risk. Based on exposure to humans, inhalation of respirable dust particles represents a relatively insignificant portion of the total exposure (i.e., less than 5 percent; USEPA, 2005b). Inhalation pathways likely result in negligible contributions to overall exposure relative to ingestion pathways; therefore, inhalation exposures were not evaluated quantitatively in the BERA.

3.3.5 *Hydrologic Variability and Spatial and Temporal Trends in Surface Water Cyanide and Fluoride*

The Phase II Sampling and Analysis Plan (SAP) (Roux, 2018a) evaluated hydrologic variability in conjunction with spatial and temporal trends of surface water cyanide and fluoride concentrations. This assessment used long-term records of stream discharge measurements from the Flathead River, precipitation data from Kalispell Airport, and analytical results from the Phase I Site Characterization (Roux, 2017a) to elucidate how temporal variations in hydrologic condition may influence subsequent investigations of cyanide and fluoride in aquatic exposure areas of the Flathead River and its adjacent riparian zone. A summary of key findings from the Phase II SAP assessment (Roux, 2018a) are discussed

below. Additional findings for the complete Phase I and Phase II Site Characterization datasets are presented in **Section 4.1.2** and in **Section 6.3.1**.

The assessment of discharge data from the Flathead River indicated that average monthly discharge patterns for 2016 and 2017 were generally consistent with the 10-year monthly discharge pattern from 2008 to 2017 (Roux, 2018a). Over the 10-year period, maximum discharges typically occurred in May and June and minimum discharges were noted between October and March. During Phase I Site Characterization sampling in 2016 and 2017, maximum and minimum discharge events occurred within a representative time frame that is consistent with historical data (**Figure 3-5**). The 2016 Phase I sampling period was characterized by a lower than average monthly discharge, except for October and November. In 2017, monthly discharge was higher than average. In addition, the 2017 discharge within the Flathead River had greater extremes in both maximum and minimum monthly discharge than the 10-year average.

Spatial and temporal trends were observed in surface water fluoride and cyanide collected during the Phase I Site Characterization (Roux, 2017a). The BERA Work Plan (EHS Support, 2018) further discussed the temporal variability and spatial gradient in surface water fluoride and total cyanide concentrations in the Backwater Seep Sampling Area and downstream stations in the Flathead River over the four Phase I sampling events. Spatial and temporal trends noted in the Phase II SAP and BERA Work Plan are discussed below.

Spatial trends observed followed the general pattern of elevated concentrations of cyanide and fluoride in the Backwater Seep Sampling Area, which exhibited attenuation in the downstream direction. Concentrations in samples collected from the downstream portion of the Flathead River, outside of the Backwater Seep Sampling Area, rapidly reached undetectable levels immediately downgradient of the seep area itself. The greatest surface water concentrations of total cyanide and fluoride were generally observed at station CFSWP-005. During all sampling rounds of the Phase I investigation, surface water concentrations of total cyanide and fluoride decreased with increasing distance downstream.

Temporal trends were associated with flow condition in the Flathead River. Wet periods of high discharge were characterized by lower concentrations of cyanide and fluoride, with the opposite observed during low water. The greatest surface water concentrations of total cyanide and fluoride were generally observed at station CFSWP-005 when discharge in the Flathead River was low (Phase I – Round 1 and Round 2). Surface water concentrations at CFSWP-005 decreased for fluoride and to a lesser extent during high-water sampling events (Phase I – Round 3 and Round 4). This evaluation suggested that potential exposure to total cyanide and fluoride in surface water in the Backwater Seep Sampling Area was greatest during low-flow sampling events in the Flathead River (September through December). Temporal patterns also seemed to influence the relative decrease in surface water concentrations moving downstream suggesting that interactions between flow magnitude and position was occurring. Rapid attenuation with distance was noted, particularly for cyanide, which was non-detect in sample stations within the Flathead River itself. These interaction effects were explored as part of this investigation and discussed in greater detail in **Section 4.1.2** and in **Section 6.3.1** for the complete Phase I and Phase II Site Characterization datasets.

The temporal evaluation of total cyanide and fluoride concentrations in Phase I surface water samples from other aquatic and transitional exposure areas of the Site indicated some seasonal variability in fluoride concentrations. However, variability in total cyanide concentrations did not indicate a clear seasonal pattern due to the low concentrations that were observed.

3.3.6 Ecological Receptors of Concern

The ecological exposure areas identified in **Section 3.3.1** may support multiple ecological receptors of concern. Aquatic receptors of concern that may use habitats within aquatic and/or transitional exposure areas include plants, invertebrates, fish, herptiles, and semi-aquatic birds and mammals. Terrestrial receptors of concern that may use habitats within aquatic, transitional, and/or terrestrial exposure areas include plants, invertebrates, herptiles, and terrestrial birds and mammals.

Several surrogate species were identified as representative species to evaluate exposure to mammalian and avian receptors based on feeding guild. Representative terrestrial species for each receptor group based on feeding guild are provided below.

Receptor Group	Scientific Name	Common Name
Mammalian Fauna		
Herbivorous Mammal	*Microtus pennsylvanicus*	Meadow Vole
Insectivorous Mammal	*Blarina brevicauda*	Northern Short-tailed Shrew
Carnivorous Mammal	*Mustela frenata*	Long-tailed Weasel
Avian Fauna		
Herbivorous Bird	*Zenaida macroura*	Mourning Dove
Invertivorous Bird	*Scolopax minor*	Woodcock
Carnivorous Bird	*Buteo jamaicensis*	Red-tailed Hawk

Representative aquatic/semi-aquatic species for each receptor group based on feeding guild are provided below.

Receptor Group	Scientific Name	Common Name
Mammalian Fauna		
Piscivorous Mammal	*Mustela vison*	Mink
Avian Fauna		
Invertivorous Bird	*Cinclus mexicanus*	American Dipper
Piscivorous Bird	*Megaceryle alcyon*	Belted Kingfisher

The focus of evaluation for each exposure area is dependent upon the habitat present and the receptors that are likely to utilize that habitat. **Table 3-1** presents a qualitative assessment of potential use of exposure areas based on the specific habitat requirements of identified receptors of concern. For terrestrial exposure areas, the risk characterization focused on organisms that have a majority of their exposure associated with terrestrial exposure pathways (i.e., all receptors except the mink, American dipper, and belted kingfisher). Similarly, the focus of aquatic exposure areas was those receptors who primarily ingest prey living in the water column or benthos. Transitional exposure areas evaluate all receptors, as both terrestrial and aquatic species may utilize the habitat during periods of inundation and dry conditions. Plant, invertebrate, and herptile communities were also evaluated, where appropriate, based on the availability of published toxicity data for organisms that occupy similar niches.

The United States Fish and Wildlife Service Information for Planning and Consultation (USFWS IPaC; https://ecos.fws.gov/ipac) indicated that six federally threatened (or proposed threatened) species may occur at the Site. No federally endangered species were identified by the USFWS IPaC search. The six federally threatened (or proposed threatened) species identified by USFWS IPaC are presented in the following table, along with general habitat requirements.

Scientific Name	Common Name	Status	Potential Exposure Area – General Habitat Requirements
Mammals			
Lynx canadensis	Canada Lynx	Threatened	Terrestrial – Moist, boreal spruce-fir forest habitat, particularly dense stands of young conifers.
Ursus arctos horribilis	Grizzly Bear	Threatened	Terrestrial – Relatively undisturbed mountainous habitat ranging from dense forest to subalpine meadows.
Gulo gulo luscus	North American Wolverine	Proposed Threatened	Terrestrial – High elevation habitat near the tree-line, typically in remote areas.
Birds			
Coccyzus americanus	Yellow-billed Cuckoo	Threatened	Terrestrial – Dense, wooded habitats with cover and water nearby, particularly cottonwood-dominated forests canopies.
Fish			
Salvelinus confluentus	Bull trout	Threatened	Aquatic – Cold-water, clean lake and stream habitats, with complex habitat features (e.g., riffles, pools, undercut, banks, structure).
Plants			
Silene spaldingii	Spalding's Catchfly	Threatened	Terrestrial – Bunchgrass grasslands and sagebrush-steppe, and occasionally in open-canopy pine stands.

The USFWS IPaC also indicated that critical habitats for the federally threatened bull trout and eight migratory USFWS Birds of Conservation Concern may occur at the Site. The migratory Birds of Conservation Concern are presented in the following table.

Scientific Name	Common Name	Breeding Season
Carpodacus cassinii	Cassin's Finch	May 15 – July 15
Aechmophorus clarkii	Clark's Grebe	All year
Tringa flavipes	Lesser Yellowlegs	Breeds Elsewhere
Numenius Americanus	Long-billed Curlew	April 1 – July 31
Limosa fedoa	Marbled Godwit	May 1 – July 31
Contopus cooperi	Olive-sided Flycatcher	May 20 – August 31
Selaphorus rufus	Rufous Hummingbird	April 15 – July 15
Tringa semipalmata	Willet	April 20 – August 5

3.3.7 Ecotoxicity of Primary Constituents of Potential Concern

The results of the Phase I and Phase II Site Characterization (Roux, 2017a and 2019) and SLERA (Roux, 2017b) indicated that cyanide, fluoride, and PAHs are the primary COPCs identified within the potential source areas and site features. Metals were also frequently detected in site media at maximum concentrations exceeding conservative ESVs in the SLERA. The following sections present a review of the ecotoxicity of these constituent groups in aquatic, transitional, and terrestrial exposure areas identified at the Site.

3.3.7.1 Cyanide

Cyanide is a general term that is used to refer to several compounds that contain a carbon-nitrogen functional group where the two atoms are bound together with a triple bond. Cyanide occurs in multiple forms in the environment. In water, cyanide can occur in strong and weak metal-cyanide complexes, as cyanate or thiocyanate, organocyanides, or as free cyanide. In solid phases, cyanides can occur in simple metal cyanide solids, complexes with alkali earth metals, or in complexes with other metals (Jaszczak et al., 2017). The toxicity of cyanide depends on its form. Free cyanide, including the liberated anion of cyanide ($^{-}$CN) as well as hydrogen cyanide (HCN), and soluble cyanide salts are the most acutely toxic forms of cyanide.

During the aluminum reduction process many chemical reactions can take place within the smelting potliner, which consists of the refractory lining, carbon cathode, and carbon sidewalls. Some of the chemical reactions that take place within pot lining materials are responsible for the production of cyanide compounds. Cyanide, along with other potentially hazardous compounds such as fluorides, can accumulate within the potliner during its operational lifespan. Once the liner has reached its operational lifespan and is removed from the pot lines, it is considered spent potliner (SPL), which is regulated as hazardous waste by the USEPA (Silveira et al., 2002). The presence of sodium-cyanide (NaCN) in SPL is of greatest concern because it is a soluble cyanide salt. Other less-soluble cyanide compounds, such as sodium ferrocyanide, are also present in large quantities within SPL (Courbariaux et al., 2004). Lisbona et al. (2012) determined the soluble cyanide fraction of SPL using a water washing approach; approximately 20 percent of the total cyanide within the studied SPL was soluble.

The primary mode of toxicity of cyanide compounds is disruption of cellular respiration. More specifically, cyanide causes histotoxic hypoxia, or the inability for cells to take up oxygen. The

mechanism that causes disruption to cellular respiration is free cyanide binding with the trivalent iron within cytochrome oxidase, an essential enzyme in the electron transport chain. Once bound, the synthesis of adenosine triphosphate (ATP) ceases and cellular function ceases due to the lack of energy (Jaszczak et al., 2017). Cyanide ions can also affect other enzymatic paths in flora and fauna (Ebbs, 2004), and react with hemoglobin (Lanno and Menzie, 2006). The ecotoxicity of cyanide is discussed for aquatic and terrestrial receptors below.

Aqueous forms of cyanide in the aquatic environment are broadly categorized into four classes: free cyanide, metal-cyanide complexes, cyanate/thiocyanate species, and organocyanide compounds (Ghosh et al., 2006). Metal-cyanide complexes may be further divided into weak metal-cyanide complexes and strong metal cyanide complexes. The dissociation of metal-cyanide complexes is dependent on pH, temperature, and reduction-oxidation potential. Weak acid dissociable (WAD) complexes with certain transition metals (Cu, Ag, Zn, Cd, Ni, and Hg) dissociate under weak acid pH (approimately 4.5); metal-cyanide complexes with other transition metals (Au, Fe, Pt, Pd, and Co) are highly resistant to dissociation and only dissociate under strong acid conditions (pH approximately 1-2) and high temperatures (100 ^{o}C). Several metal-cyanide complexes are known to be photochemically reactive. In the presence of ultraviolet (UV) light, the photolysis of ferrocyanide and ferricyanide complexes results in the formation of free cyanide, as HCN. The rate of photochemical dissociation is dependent on pH, free cyanide concentration in solution, UV intensity, temperature, turbidity, water column depth (Ghosh et al., 2006). Toxic free cyanide (HCN + $^{-}$CN) formed through photodegradation or other mechanisms does not tend to persist in aquatic environments because rapid biodegradation or volatilization occurs within the water column. Free cyanide can be oxidized to form cyanate ($^{-}$CNO) or react with sulfur to form thiocyanate ($^{-}$SCN), which are relatively nontoxic in comparison with free cyanide (Ghosh et al., 2006).

Cyanide exposure in aquatic environments occurs through direct contact with and ingestion of cyanide-containing water. This exposure occurs through ingestion or rapid gill uptake by aquatic organisms. Semi-aquatic organisms can also be exposed through drinking cyanide-containing water. Exposure to less soluble forms of cyanide in water (WAD complexes) may be problematic to mammalian and avian receptors, because cyanide can be liberated in the stomach due to the acidic and anoxic conditions. Incidental ingestion of cyanides in sediment is not a significant exposure pathway because free cyanide and weak metal–cyanide complexes tend to not accumulate in sediments unless organic carbon is abundant (Higgins and Dzombak, 2006). The reactive nature of free cyanide in water and its acute toxicity to (and rapid metabolism within) organisms limits the potential for bioaccumulation (Eisler, 1991; Lanno and Menzie, 2006). Species mean acute toxicity values for 28 freshwater species ranged from 0.046 to 10 milligrams of cyanide per liter (mg CN/L) (Lanno and Menzie, 2006). Chronic data are much more sparsely available for cyanide, and chronic toxicity values ranged between 0.008 and 0.079 mg CN/L for five freshwater and two marine species (Lanno and Menzie, 2006).

In terrestrial environments, free cyanide is typically not present. Upon entering the soil matrix via groundwater or deposition, free cyanide is rapidly complexed with metals to form cyanide-metal complexes, metabolized through microbial processes, or volatilized (Lanno and Menzie, 2006). Because cyanide compounds do not typically bioaccumulate, direct contact exposure and incidental ingestion of soils containing cyanides are the primary exposure routes for cyanides in terrestrial organisms. The mode of toxicity of cyanide to terrestrial plants is similar to that of fauna. Enzymatic binding to cytochrome oxidase results in cessation of cellular electron transport (Yu, 2015). Some plant species can assimilate or metabolize cyanide, and phytoremediation techniques as a means to cleanup terrestrial cyanide have been extensively studied (Yu, 2015).

The literature regarding cyanide bioavailability and toxicity summarized in this section was used to support the development of ecological benchmark concentrations for relevant exposure media in an interim deliverable (**Appendix A1**), as well as the Effects Analysis of this BERA.

3.3.7.2 Fluoride

Fluoride is naturally abundant in soils and contained in the minerals apatite ($Ca_5(PO_4)_3F$), fluorite (CaF_2), cryolite (Na_3AlF_6) and micaceous clay materials. Potassium fluoride (KF) and sodium fluoride (NaF) are soluble salts that contain fluoride. The fluoride-containing feedstocks used in smelting include fluorite, aluminum fluoride (AlF_3), and cryolite. Synthetic cryolite is the predominate flux compound used in aluminum smelting. Fluorite has the lowest solubility in water (16 milligrams per liter [mg/L] at 20 degrees Celsius) and cryolite is also relatively insoluble in water (420 mg/L at 20 degrees Celsius). Aluminum fluoride has an increased solubility in water of 6,700 mg/L at 20 degrees Celsius. KF and NaF represent the most soluble sources of fluoride with solubility in water at 20 degrees Celsius of 95,000 mg/L and 40,400 mg/L, respectively. NaF and KF are often used in toxicity testing of fluoride for both aqueous and solid matrices. The ecotoxicity of fluoride is discussed for aquatic and terrestrial receptors below.

Aquatic invertebrates and fish tend to take up fluoride directly from water, and, to a lesser extent, from consumption of organisms that contain fluorides. Fluorides can bioaccumulate within aquatic organisms, typically in exoskeletons for invertebrates and skeletal bones in fish. In aquatic flora, fluoride can accumulate in plant and root tissues.

The toxic action of fluoride is linked to the strong electronegative state of fluoride ions, which act as enzymatic poisons. Key enzymes, for which their activity can be compromised by the presence of fluoride ions include: phosphatase, hexokinases, enolase, succinic, dehydrogenase, pyruvic oxidase, and others (Camargo, 2003). The decreased enzymatic activity results in interruption of key metabolic processes, such as glycolysis and protein synthesis (Kessabi, 1984). The specific mechanism that causes the decoupling of metabolic processes due to enzymatic activity inhibition is not fully understood.

Increased fluoride concentration, exposure time, and water temperature increases the toxic effects of fluoride to aquatic invertebrates (Camargo, 2003). Inorganic fluorides in solution can be removed from the aquatic phase by precipitation in the presence of calcium carbonate, calcium phosphate, calcium fluoride and, magnesium fluoride (Stumm and Morgan, 1996). Therefore, harder or more saline water tends to be less toxic to aquatic invertebrates. An evaluation of available literature for freshwater acute and chronic effect endpoint data indicated that *Hyalella azteca,* an amphipod, exhibits the greatest sensitivity to fluoride among the freshwater invertebrate species used for toxicological testing. The 10 and 50 percent inhibition concentrations (IC_{10} and IC_{50}) based on growth inhibition were 1,800 and 4,100 micrograms of fluoride per liter (µg F/L), respectively at a hardness of 90 mg/L $CaCO_3$ and chloride content of 2,000 micrograms of chloride per liter (µg Cl/L) (Pearcy et al., 2015).

Increased fluoride concentration, exposure time, and water temperature also increases the toxic effects of fluoride to fish (Camargo, 2003). However, increasing intraspecific fish size and increasing calcium and chloride concentrations in water tends to decrease the toxic effects of fluoride to fish. Based on recent work by Pearcy et al. (2015), it appears that chloride concentration in surface water has a greater influence on the reduced toxicity of fluoride to freshwater organisms than calcium carbonate. Chloride concentration in water does reduce the toxic effects of fluoride to certain species; however, chloride does not mitigate toxic effects for all species. An evaluation of available literature for freshwater acute

and chronic effect endpoint data indicated that *Oncorhynchus mykiss*, the rainbow trout, exhibits the greatest sensitivity to fluoride among the freshwater fish species used for toxicological testing. The IC_{10} and IC_{50} were 6,000 and greater than 64,100 µg F/L, respectively, at a hardness of 6 mg/L $CaCO_3$ and chloride content of 2,000 µg Cl/L (Pearcy et al., 2015).

Depending upon concentration, exposure time, and species, fluoride can have inhibitory or enhancing effect on freshwater algal growth (Camargo, 2003). Like terrestrial plants, fluoride content in aquatic macrophyte tissue increases with increasing water concentration and exposure time. An evaluation of available literature for freshwater acute and chronic effect endpoint data for aquatic plants indicated that *Chlorella vulgaris,* a green algae, exhibits a sensitivity to fluoride. The non-inhibitory concentration and lethal concentration in 50 percent of the test organisms (LC_{50}) were 66,500 and 380,000 µg F/L, respectively at a pH of 6.8 (Rai et al., 1998).

In terrestrial environments, fluoride can have effects on plant roots and aboveground vegetation depending on uptake mechanisms, as well as the age and source of fluoride. Plants can take up fluorides from soil and transfer them to foliar tissues through xylematic flows (Fornasiero, 2001). When taken up by roots, some residual fluoride is accumulated into root tissue; however, much of the fluoride is transported to shoot or leaf biomass (Jha et al., 2009).

In addition to potential uptake from soil, gaseous fluorides can be absorbed through leaf stomata and be transferred to foliar tissues through xylematic flows (Zouari et al., 2014). When exposure is predominately atmospheric, accumulation of fluoride in plant roots is much less than when exposure is predominately through soil sources (Baunthiyal et al., 2014). However, the uptake of fluoride into foliar tissue has been shown to decrease, coincident with decreasing atmospheric fluoride concentrations. For example, Horntvedt (1995) found no apparent long-term effects in spruce and pine needles from fluoride accumulation into foliar tissues over a period of approximately 25 years with coincidental decreases in atmospheric fluoride emissions. This suggests that both the age and source of fluoride contamination may affect its uptake and toxicity within the terrestrial environment.

The most common visible symptom of fluoride toxicity in terrestrial plants is foliar damage (leaf necrosis). This occurs due to several morphological modifications to the upper and lower epidermis. Collapse of mesophyll results in cell distortion and sharpening (Fornasiero, 2001). Leaf necrosis can occur along the leaf margin (sides) or at the tip of the leaf (apical leaf necrosis).

High internal fluoride concentrations affect multiple physiological and metabolic plant processes (Yadu et al., 2016). Elevated fluoride can reduce growth and development, affect rates of photosynthesis, and disrupt multiple enzymatic processes. However, the effects of fluoride on growth and development of terrestrial plants vary considerably between species (Baunthiyal et al., 2014). Coniferous trees have been identified as sensitive plant species for exposure to fluoride. Zwiazek and Shay (1988) reported a lowest observed effect concentration (LOEC) for *Pinus banksiana* (jack pine) seedlings for growth of 3 mg F per kilogram (kg) dry weight (dw) of sand. Effects were observed after 29 hours. Arnesen (1997) reported a LOEC for *Lolium muliflorium* (ryegrass) growth of 400 mg F/kg dw.

The effect of fluoride on terrestrial invertebrates is not as well studied as the effects on plants and higher trophic levels. Increased fluoride concentration and exposure time has been shown to increase fluoride body burden to the terrestrial invertebrate *Eisenia fetida* (Lawson and Yu, 2003). The accumulation of fluoride by numerous other invertebrates from fluoride contaminated soils has also been studied (Buse, 1986).

The fluorination of soils by the addition of super phosphate fertilizers (e.g., monocalcium phosphate, $Ca(H_2PO_4)_2$) has resulted in many studies which focus on the effects of fluorides on grazing animals such as sheep and cows. Ingestion is the primary exposure route for fluoride in higher trophic level organisms. Fluoride compounds are absorbed in the stomach and small intestine, where acidic conditions can convert recalcitrant forms of fluoride into more bioavailable forms (Cronin et al., 2000). Threshold soil fluoride concentrations for cattle and sheep were between 326 and 1,085 mg F/kg soil dw and 372 and 1,461 mg F/kg soil dw, respectively. More recent evaluation of terrestrial exposure by Pascoe et al. (2014) found that the lowest no observed adverse effects level (NOAEL) and lowest observed adverse effects level (LOAEL) risk-based concentrations were 149 mg F/kg soil dw and 659 mg F/kg soil dw, respectively.

One key consideration to the ecotoxicity of fluoride in soils is the degree to which fluoride is adsorbed to soil particles. Fluoride adsorption is greatest in acidic non-calcareous soils containing aluminum hydroxides, where fluorides occur predominantly as aluminum fluorosilicate complexes (Pascoe et al. 2014). In slightly alkaline soils with sufficient calcium carbonate ($CaCO_3$), soluble fluoride would be most likely completely fixed as CaF_2 (Brewer, 1966) and less bioavailable. However, an increasing electrostatic potential at even higher pH decreases the retention of fluoride on the soil and increases solubility. This is partially attributed to the displacement of adsorbed fluorine by the increased concentration of hydroxide ions (Larsen & Widdowson, 1971).

The literature regarding fluoride bioavailability and toxicity summarized in this section was used to support the development of ecological benchmark concentrations for relevant exposure media in an interim deliverable to the BERA Work Plan (**Appendix A1**), as well as the Effects Analysis of the BERA Report. The derivation of ecological benchmark concentrations considers the site-specific conditions in terrestrial, transitional, and aquatic exposure areas that may influence fluoride bioavailability and toxicity to representative ecological receptors.

3.3.7.3 Polycyclic Aromatic Hydrocarbons

PAHs are a group of organic compounds that contain at least two condensed aromatic ring structures. When a PAH has three or less condensed aromatic rings, it is considered a low molecular weight PAH (LMW PAH). When it has four or more aromatic rings, it is considered a high molecular weight PAH (HMW PAH; USEPA, 2007a). During the production of aluminum using the Hall-Héroult process, carbon anodes and cathodes are used to conduct electricity through the alumina to produce molten aluminum. The coal tar pitch and coke used to create carbon anodes and cathodes contain multiple PAH compounds. The ecotoxicity of PAHs in aquatic and terrestrial environments are discussed below.

In aquatic environments, it is generally accepted that PAH compounds exert toxicity to benthic invertebrates primarily by a narcosis mode of action (USEPA, 2003a; DiToro et al., 2000; Swartz et al., 1995; Russom et al., 1997; McGrath et al., 2004). Narcosis is a nonspecific, reversible disruption of neural activity (i.e., anesthesia). Based on the similar mode of action of PAH compounds, the toxicity of multiple PAH compounds in a sediment mixture is approximately additive; therefore, exposure to the PAH mixture must be evaluated to assess potential toxicity in sediment (USEPA, 2003a). The composition of individual compounds within PAH mixtures and the relative contribution of those compounds to the additive toxicity to the benthic community vary depending on the source of PAHs.

Additional modes of ecotoxicity include phototoxicity, whereby exposure to UV light increases the toxicity of PAHs. Phototoxicity has been demonstrated in aquatic environments (van Brummelen et al.,

1998; Weinstein and Polk, 2001). However, comparisons by Swartz et al. (1995) suggest that responses of benthic communities in PAH-contaminated sites correlate well with the toxicity that is predicted based on narcosis, suggesting that phototoxicity was not a major confounding factor for those environments.

Similar to aquatic receptors, the primary mode of toxicity of PAHs to terrestrial invertebrates is through narcosis (Sverdrup et al., 2002). Soluble phases of PAH compounds found in interstitial pore waters present the greatest risk to invertebrates through ingestion or incidental ingestion. For LMW PAHs, 10 percent effect concentrations (EC_{10}) for reproduction or growth for several invertebrate species ranged from 8 to 113 milligrams per kilogram (mg/kg) dw, whereas the EC_{10} or the maximum acceptable toxicant concentration (MATC) for soil invertebrates exposed to HMW PAHs ranged from 10 to 80 mg/kg dw (USEPA, 2007a). Higher molecular weight PAH compounds generally exhibit greater toxicity to organisms, particularly mammals due to the carcinogenic and mutagenic properties. Mammalian insectivores, the most sensitive receptor group, can have a variety of physiological responses to PAH exposure (USEPA, 2007a).

The literature regarding PAH bioavailability and toxicity summarized in this section was used to support the development of ecological benchmark concentrations for relevant exposure media in an interim deliverable (**Appendix A**), as well as the Effects Analysis of the BERA Report. The derivation of ecological benchmark concentrations will consider the site-specific conditions in terrestrial, transitional, and aquatic exposure areas that may influence PAH bioavailability and toxicity to representative ecological receptors.

3.3.7.4 Metals

The availability of metals to be incorporated into biological tissues does not necessarily correspond with the total concentration of metals in soil, sediment, or surface water; bioavailability is directly related to the speciation of metals. For most divalent metals, the most bioavailable and toxic forms of metals are the metal ions or small metal-anion complexes, which are present at very low concentrations in the environment.

In sediments, most metals are not available for uptake due to strong complexation by solid phases. For example, metals precipitated as metal-sulfide ligands may be resistant to solubilization under typical geochemical conditions observed in sediment or sediment pore water (Sigg and Behra, 2005). The soluble phase of metal ions in sediment pore water is generally the most bioavailable and potentially toxic form to ecological receptors. Equilibrium partitioning theory may be used to predict the bioavailability toxicity of metals in sediment based on the partitioning of simultaneously extracted metals (SEM) between acid volatile sulfides (AVS), total organic carbon (TOC), and pore water (USEPA, 2005a). In reduced sediments, free metal ions partition to AVS and TOC to form insoluble metal sulfide complexes that have low bioavailability and are associated with low toxicity to benthic organisms in toxicity tests (USEPA, 2005a). Metals concentrations directly measured in filtered pore water samples represent the dissolved fraction of metals, which is bioavailable and can be incorporated into the tissues of benthic invertebrates (USEPA, 2005a).

Many metal compounds are essential to maintaining cellular homeostasis. However, when metal concentrations exceed what is needed to maintain normal organismal functions, toxic effects can occur (Valko et al, 2005). Metal-induced toxicity can occur by several mechanisms in organisms, including hepatotoxicity (liver toxicity), neurotoxicity (brain toxicity), and nephrotoxicity (kidney toxicity). Iron,

copper, chromium, vanadium, and cobalt can undergo redox-cycling reactions that can lead to deleterious types of oxidative stress. Mercury, cadmium, and nickel can deplete glutathione, which is an essential antioxidant in organisms. Arsenic primarily acts on organisms by binding to thiols, which can disrupt important enzymatic functions (Valko et al, 2005). The ability of metals to bioaccumulate within organisms varies depending on the receptor group and type of metal. Some metals biomagnify (e.g., mercury), or increase in concentration within receptor tissues moving up to higher trophic level.

The literature regarding the bioavailability and toxicity of metals summarized in this section was used to support the development of ecological benchmark concentrations for relevant exposure media in an interim deliverable (**Appendix A**), as well as the Effects Analysis of the BERA Report. The derivation of ecological benchmark concentrations will consider the site-specific conditions in terrestrial, transitional, and aquatic exposure areas that may influence metal bioavailability and toxicity to representative ecological receptors.

3.4 SLERA Refinement of Constituents of Potential Ecological Concern

A refinement of COPECs identified in the SLERA was conducted based on the Phase I Site Characterization data (Roux, 2017b) to identify and provide context for those constituents that are likely to be focal COPECs in the BERA process. Refinement steps included consideration of additional factors that support the removal of some screening-level COPECs from further consideration because they are highly unlikely to adversely impact ecological receptors. The results of this refinement of COPECs identified in the SLERA based on Phase I sampling results was presented in the BERA Work Plan (EHS Support, 2018). The results of that refinement were used to inform decisions regarding the collection and analysis of Phase II data. However, because this BERA investigation includes a re-analysis of all of the ecological risk assessment steps based on the combination of Phase I and Phase II Site Characterization data, the results of the SLERA COPEC refinement are not presented in this document. Screening-level and refined selections of BERA COPECs based on the combined Phase I and Phase II Site Characterization datasets are presented in **Section 4.3** through **Section 4.5**.

3.5 Data Quality Objectives

Following the initial SLERA, the Phase II Site Characterization SAP (Roux, 2018a) presented the detailed study design and supporting data quality objective (DQO) process to evaluate site-specific ecological risk based on identified assessment endpoints, risk questions, and measurement endpoints defined in the baseline problem formulation. The development of the study design in the Phase II Site Characterization SAP was guided by the USEPA DQO process, which is a seven-step planning approach to develop sampling designs for data collection activities that support decision making (USEPA, 2000a). Per USEPA (1997), the goals of the DQO process in the context of ERAGS are to:

- Clarify the study objective and the most appropriate types of data to collect.
- Determine the most appropriate field conditions under which to collect the data.
- Specify acceptable criteria that will be used as the basis for establishing the quantity and quality of data needed to support risk management decisions.

As part of the Phase II Site Characterization SAP, a DQO-based sample size evaluation was conducted to approximate the minimum sample sizes needed to estimate unknown population parameters (e.g., mean, upper confidence limits of the mean [UCL_{mean}]) of COPECs and COPCs in soil to support the BERA and Human Health Risk Assessment (HHRA), respectively (Roux, 2018a).

3.6 BERA Conceptual Study Design

The conceptual study design for the BERA was presented in the BERA Work Plan (EHS Support, 2018) and incorporated into the Phase II Site Characterization SAP (Roux, 2018a). The design identified key data objectives for the Phase II Site Characterization to support the evaluation of assessment endpoints and risk questions based on defined measurement endpoints identified in the BERA problem formulation for aquatic, transitional, and terrestrial exposure areas at the Site.

The BERA Work Plan (EHS Support, 2018) presented an analysis of data gaps identified in the SLERA and developed a conceptual plan for collecting additional data during the Phase II Site Characterization to support the BERA process. This conceptual plan outlined the strategy to collect additional data during the Phase II Site Characterization that would provide the spatial adequacy, vertical characterization of soil in ecological depths of exposure, sufficient sample size, and information related to COPEC bioavailability in a particular medium necessary for developing sound conclusions about the potential for ecological risk at the site. These objectives were obtained by:

- Collecting soil samples within the 0 to 0.5 and 0.5 to 2 feet below ground surface (ft-bgs) intervals at all exposure areas (the BERA Work Plan [EHS Support, 2018] provided justification for this soil depth as the relevant soil interval for ecological risk based on receptor exposure patterns and an evaluation of Phase I data that indicated generally decreasing concentrations with increasing soil depths for most constituents at most locations). A similar evaluation was performed after the Phase II samples were collected and analyzed. As described in the DSR, samples collected at depth intervals deeper than 2 ft-bgs for key site contaminants had average concentrations that were an order of magnitude or lower than concentrations detected within the 0 to 2 ft-bgs interval (see Section 4.2.1.11 in Roux, 2019). Thus, the assumption that exposure point concentrations based on data from the 0 to 2 ft-bgs interval provides a conservative estimate of exposure to ecological receptors was confirmed by the analysis of Phase I and Phase II Site Characterization datasets.
- Ensuring that enough samples (generally 8 to 10 samples, at a minimum) were collected in each exposure medium in each exposure area to calculate 95 percent UCL_{mean} based on the DQO-based minimum sample size evaluation.
- Collecting data to evaluate the bioavailability of constituents to ecological receptors, such as collecting both filtered and unfiltered surface water data, analyzing soil samples for parameters (e.g., pH, organic carbon) that affect the potential for binding constituents in the medium matrix in non-bioavailable forms, and analyzing sediment pore water and acid volatile sulfides-simultaneously extracted metals (AVS-SEM) in sediment.

3.6.1 Aquatic Exposure Areas

Surface water analyses in aquatic exposure areas included analyses of filtered (dissolved) and unfiltered samples for metals, cyanide, free cyanide, and fluoride. Consistent with the analyses of pore water in sediment, the freely dissolved fraction is a better indicator of potential bioavailability and toxicity of COPECs in surface water. Surface water analyses included the analysis of free cyanide, which is more representative of the bioavailable and toxic form of cyanide. Free cyanide analysis of surface water provides a 'snapshot' of the bioavailable and toxic form of cyanide in the water at any one time. Under different environmental conditions (e.g., ultraviolet light exposure, temperature, pH), different concentrations of free cyanide may be present depending on the cyanide liberated from metal cyanide complexes and the amount of hydrogen cyanide volatilized off. The sampling programs implemented as

part of the Phase I and Phase II Site Characterization in areas where elevated cyanide have been detected were designed to provide comprehensive datasets to characterize the spatial and temporal variability in free and total cyanide concentrations in surface water under varying environmental conditions.

The BERA Work Plan provided for the evaluation of the bioavailability and toxicity of COPECs in sediment within aquatic exposure areas using a tiered approach that is consistent with framework presented in USEPA guidance for evaluating ecological risk to benthic receptors from PAHs in sediment (USEPA, 2009). The tiered approach is applicable to the evaluation of PAHs and other organic and inorganic COPECs in sediment. The tiered approach includes the following components:

- Tier 1 – Assessment of COPEC bioavailability based on whole sediment analysis
- Tier 2 – Assessment of COPEC bioavailability based on pore water analysis
- Tier 3 – Assessment of COPEC bioavailability using the Sediment Quality Triad (SQT) approach and/or tissue analyses

Data to support Tier 1 and Tier 2 assessments were collected as part of the Phase I and Phase II Site Characterizations. The need for and scope of potential Tier 3 analyses may be further evaluated pending the outcome of the BERA.

Tier 1 analyses of COPEC bioavailability, including predictive models based on equilibrium partitioning (EqP) relationships, were completed for select constituent groups based on Phase I Site Characterization Data in the SLERA and COPEC Refinement (**Section 3.4**). Tier 1 analyses were also conducted in this BERA on additional data collected during the Phase II sampling as part of a weight-of-evidence evaluation for exposure. Predictive EqP models estimate the bioavailable fraction of COPECs in pore water based on the partitioning of COPECs between sediment organic carbon, pore water, and biota. EqP equilibrium partitioning sediment benchmarks (ESBs) represent concentrations of organic constituents in bulk sediment that, at equilibrium, would result in partitioning to sediment pore water at concentrations equivalent to a water quality benchmark (WQB) that may be based on no observed effect concentration (NOEC) or LOEC endpoints for survival, growth, or reproduction. Further refinement of these predictive approaches may be conducted as part of Tier 1 analyses consistent with the following USEPA guidance:

- PAHs: *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures* (USEPA, 2003a)
- Divalent metals: *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: Metals Mixtures (Cadmium, Copper, Lead, Nickel, Silver, and Zinc)* (USEPA, 2005a)
- Nonionic Organic Compounds: *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: Compendium of Tier 2 Values for Nonionic Organics* (USEPA, 2008a)

For organic COPECs lacking ESB values from the above sources, site-specific ESBs may be derived using the sample-specific fraction of organic carbon (f_{oc}), constituent-specific organic carbon-water partitioning coefficient (K_{oc}), and WQB based on the following EqP relationship:

$$ESB = (f_{oc} \times K_{oc} \times WQB)$$

where:

ESB = EqP Sediment Benchmark (µg/kg dw sediment)

f_{oc} = Sample-specific fraction of organic carbon in sediment
K_{oc} = Organic carbon-water partitioning coefficient (L/kg)
WQB = Water quality benchmark (µg/L)

The use of conservative partitioning coefficients and WQB values in predictive EqP models minimizes the potential for false negatives (i.e., erroneously eliminating a constituent from further consideration) in the Tier 1 analyses.

Tier 2 analyses were conducted as part of the Phase II Site Characterization in aquatic exposure areas where Tier 1 analyses indicate the potential for adverse ecological effects based on predictive models. Tier 2 analyses consist of the direct measurement of the freely dissolved COPEC fraction in sediment pore water and direct measurements of bioavailable fractions in bulk sediment. The freely dissolved fraction better predicts COPEC bioavailability and toxicity in sediment when compared to bulk sediment analyses. Direct measurements of COPEC concentrations in pore water provide an empirical measurement to supplement the conservative theoretical estimate of COPEC concentrations in pore water derived from predictive EqP models.

In addition to pore water analyses, analyses of bioavailable fractions in sediment are considered in Tier 2 analyses. Measurements of AVS-SEM were collected during the Phase II investigation in inundated or saturated sediments where divalent metals may be elevated above sediment ESVs based on total recoverable analyses (USEPA, 2005a). Soluble fluoride was also analyzed in sediment to evaluate the potential bioavailability and toxicity of fluoride to benthic organisms.

3.6.2 Terrestrial Exposure Areas

The bioavailability of metals, cyanide, fluoride, and PAHs in soils is complex and influenced strongly by pH, cation exchange capacity (CEC), organic matter content, localized hydrology, and grain size. Soil pH is considered the primary soil variable, because it controls many soil biogeochemical processes and has a significant influence on constituent bioavailability (USEPA, 2007b). Depending on COPEC speciation, and whether it is complexed or sorbed to organic matter or clay, some portion of soil COPECs may not be bioavailable because they do not readily dissolve in water or solubilize during passage through organism intestines.

The BERA Work Plan provided for the conceptual evaluation of the bioavailability and toxicity of COPECs in soils within terrestrial exposure areas based on a tiered approach:

- Tier 1 – Assessment of potential COPEC toxicity based on bulk soil analysis
- Tier 2 – Measurement of COPEC bioavailability and toxicity based on fractional analytical methods
- Tier 3 – Measurement of COPEC bioavailability and toxicity based on *in situ* toxicity studies and/or tissue analyses

The terrestrial exposure evaluations presented in the BERA are based on Tier 1 analyses that evaluate potential soil COPEC toxicity using the available Phase I and Phase II Site Characterization Data in the preliminary COPEC screen and COPEC Refinement (**Sections 4.3** through **4.5**). Tier 1 analyses included comparisons of total COPEC concentrations to ESVs and the identification of important soil physicochemical parameters that help inform soil COPEC bioavailability, particularly soil pH and soil

organic carbon content. The need for and scope of potential Tier 2 and 3 analyses may be further evaluated pending the outcome of the BERA.

3.6.3 Transitional Exposure Areas

The evaluation of the bioavailability and toxicity of COPECs in transitional exposure areas used the approaches presented in the preceding sections for aquatic and terrestrial exposure areas. The approach for transitional exposure areas was developed based on localized exposure conditions indicating the likelihood of occurrence of aquatic or terrestrial receptors.

3.6.4 Background Characterization

The adequacy of Phase I Site Characterization data collected to represent background conditions was identified as an uncertainty in the SLERA. Additional background data was collected as part of the Phase II Site Characterization to further characterize COPEC concentrations representative of regional conditions (Roux, 2019).

A Background Investigation SAP (Background SAP) (Roux, 2018b) was developed to establish the data objectives, study design, and methodologies that were used to establish a representative background dataset. As described in the Phase II Data Summary Report, (Roux, 2019) soil background locations were distal to industrial operations at CFAC and have no known waste materials present. Background soil samples were collected from similar soil types as soils identified on the Site. Surface water and sediment sampling locations targeted areas hydraulically upgradient of the Site. Background locations for aquatic environments were located upstream of the Site in locations with similar habitats and substrate characteristics to aquatic exposure areas at the Site.

Sample sizes for soil, surface water, and sediment background datasets were sufficient to develop statistically robust measurements of UCL_{mean}, as well as background threshold values (BTVs) using ProUCL software (USEPA, 2015b). Background datasets had a minimum of 8 – 10 observations for each matrix to support statistical calculations. A full description of the background area sampling and data evaluation is presented in the Phase II DSR (Roux, 2019).

4 Identification of Baseline COPECs

Following a review of the Phase II datasets, it was determined that the components and assumptions presented in the baseline risk assessment problem formulation were still valid and accurate. Although screening-level COPECs from the Phase I data were previously identified in the SLERA (Roux, 2017b), the SLERA concluded that additional samples were required to adequately characterize some portions of the site, and additional samples were collected during a second phase of sampling following the SLERA. Because the initial steps of the risk assessment that were presented in the SLERA (Roux, 2017b) and BERA Work Plan (EHS Support, 2018) were performed only on the Phase I Site Characterization data, the screening-level steps in the risk assessment process are repeated and presented in this BERA for the combined Phase I and Phase II dataset. The results of this evaluation are presented in the following sections.

Exposure areas at the Site were previously defined based primarily on the habitat type identified during the May 2016 habitat assessment (**Section 2.2.3**). These exposure areas were refined in the BERA Problem Formulation (**Section 3.3.1**) based on additional data collection and habitat evaluations that were performed following the SLERA. A total of 13 exposure areas were defined in the BERA refinement. **Figure 3-1** shows the location and extent of each exposure area. **Figures 4-1** through **4-14** present the sample locations that comprised the dataset used for each exposure area, including the incremental sampling grid area in the Operational Area of the Site (**Figure 4-8**). The screening-level COPECs in soil, surface water, and sediment that require further evaluation in each exposure area are presented in the following sections.

4.1 Evaluated Datasets

Data from samples collected in soil, surface water, and sediment during the Phase I Site Characterization, Supplemental South Pond Assessment, and Phase II Site Characterization programs were used to perform an initial screening-level identification of COPECs. The datasets for each medium are briefly discussed below. Detailed descriptions of the sampling efforts are provided in the Phase II Site Characterization Data Summary Report (Roux, 2019). The locations where the soil, surface water, and sediment samples used in the BERA were collected for each medium in each exposure area are presented in **Table 4-1** through **Table 4-13**.

4.1.1 Soils

The Phase I Site-wide soil boring and soil sampling was conducted from May 18, 2016 to August 31, 2016. Soil samples were collected utilizing either sonic-rotary methods, direct push techniques with Geoprobe™ technology, or hand auger as detailed in the Phase I Data Summary Report (Roux, 2017a). In addition, soil samples were collected from test pits conducted within the Borrow Pit area.

Three soil samples were typically collected for laboratory analyses from each soil boring within unpaved areas:

- Surface soil sample from the top 6 inches of soil
- Shallow soil sample from the interval of 0.5 to 2 ft bgs
- Intermediate depth soil sample from a depth of 10 to 12 ft bgs

In paved areas the surficial sample was omitted (due to pavement or solid surface covering) and the shallow sample was collected from the 2-foot depth interval immediately beneath the surface covering materials. At one location (CFMW-28a) adjacent to the Northeast Percolation Pond, an opportunistic soil sample was collected from a depth of 4 to 6 ft bgs based upon the observation of stained soil at that location and depth. In addition, soil samples were collected from eight test pits conducted within the Borrow Pit area in the southeast corner of the Site, with two samples collected from each test pit at depths of 0.5 to 2 ft bgs and 2 to 4 ft bgs.

For the purposes of this BERA, only soil samples collected from less than 2 ft bgs were evaluated as soils. Soils from deeper intervals are not encountered as frequently for most terrestrial receptors, particularly those that do not regularly burrow. The bioaccumulation of constituents from soils into dietary items occurs within the biologically active zone in soil where dietary items are exposed, which is generally contained within the top 1-2 ft bgs (USEPA, 2015a). Burrowing mammals may encounter and incidentally ingest soils at depths greater than 2 ft bgs within burrows. However, the analysis of Phase I and Phase II soil datasets indicates that concentrations of key constituents of concern in site soil generally decline with increasing depth (see **Section 3.6** and Roux, 2019). As a result, ecological exposure to COPECs in soils within the 0-2 ft bgs sampling intervals is typically greater than exposure to subsurface soils (greater than 2 ft bgs). Therefore, exposure estimates for direct dietary ingestion and incidental soil ingestion based on COPEC concentrations within the 0-2 ft bgs sampling intervals provide conservative estimates of exposure to mammalian receptors that potentially burrow in site soils. Soils deeper than 10 feet are not within the biologically active zone and therefore are not part of a complete exposure pathway.

Soil samples were analyzed for the following analytical suites relevant to the BERA:

- Target Compound List (TCL) VOCs (excluding surface soil samples) via USEPA Method 8260
- TCL SVOCs (including PAHs) via USEPA Method 8270
- Target Analyte List (TAL) Metals via USEPA Method 6010
- TCL PCBs via USEPA Method 8082
- TCL Pesticides (select surface samples only) via USEPA Method 8081
- Total Cyanide via USEPA Method 9012
- Fluoride via USEPA Method 300

The Supplemental South Pond Assessment soil sampling was conducted from October 31, 2017 through November 8, 2017. A total of 18 soil borings were advanced and 43 soil samples were collected within the South Percolation Pond Area. Samples were collected in accordance with the standard operating procedures (SOPs) provided in the Phase I SAP (Roux, 2015b) and the specifications of the Expedited Risk Assessment SAP (Roux, 2017d). Soil samples were packaged and shipped under chain-of-custody to Test America Laboratories, Inc. and analyzed for the following analytical suites relevant to the BERA:

- TCL VOCs (excluding surface soil samples) via USEPA Method 8260B
- TCL SVOCs (including PAHs) via USEPA Method 8270D
- TAL metals via USEPA Method 6020A / 7471B
- Total cyanide via USEPA Method 9012B
- Free cyanide via USEPA Method 9016
- Fluoride via USEPA Method 9056A

Phase II soil samples were collected from April 28, 2018 to June 28, 2018 and from September 25, 2018 to September 28, 2018. Locations and analyses were based on information obtained from the Phase I

sampling. The Phase II soil samples were analyzed for the following analytical suites relevant to the BERA:

- TCL SVOCs (including PAHs) via USEPA Method 8270 Low Level (LL)
- TAL Metals via USEPA Method 6010
- Total Cyanide via USEPA Method 9012
- Fluoride via USEPA Method 9056A
- Dioxin and furan compounds (polychlorinated dibenzo-dioxin [PCDD] / polychlorinated dibenzo-furans [PCDF]) via USEPA Method 8290A (dioxin delineation samples only)
- TCL PCBs via USEPA Method 8082 (only locations located in the vicinity of the Rectifier Yards and delineation samples within the Operational Area)
- TAL total chromium via USEPA Method 6020A, and Cr(VI) via USEPA Method 7196A (chromium speciation samples only)
- TCL VOCs via USEPA Method 8260 (four opportunistic samples only)

Additional strategies and approaches that were used to evaluate and investigate potential contamination in the soil medium are described in the following subsections.

4.1.1.1 Incremental Soil Samples

In addition to discrete soil sampling, incremental soil sampling was conducted within an area known as the Operational Area. The Operational Area comprises approximately 43 acres within the northern portion of the Main Plant Area and southern portion of the Central Landfill Area where aerial photographs indicate historical operations may have been conducted but no known source area exists. An incremental soil sampling program was conducted within the Operational Area to assess whether any potential source areas are present in this area. The work was performed in accordance with the Scope of Work outlined in the Phase I and Phase II SAPs (Roux, 2015b and 2018a) as well as SAP Field Modification #4 (described in the Phase I Data Summary Report [Roux, 2017a]).

The Operational Area soil investigation was conducted during multiple phases in the June 14, 2016 to May 23, 2018 time frame. The Operational Area was divided into 43 grid cells, also referred to as DUs, each approximately 1 acre in size. Sampling was conducted at the frequency of one incremental surface soil sample (0 to 0.5 ft bgs) and one incremental shallow soil sample (0.5 to 2 ft bgs) per DU, for a total of 43 incremental soil samples from each interval within the 43 DUs that comprise the Operational Area. Each incremental sample consisted of a composite of 32 grab samples (or “increments”) that were processed, combined, and subsampled to develop the composite ISS result as described in the Phase II SAP (Roux, 2018a). The grid where samples were collected in the Operational Area is shown on **Figure 3-1** and **Figure 4-8**. Each sample was analyzed for the laboratory analyses noted above, with the exception of VOCs. As described in the Phase I Data Summary Report, samples from the first 15 DUs (designated CFISS-001 through CFISS-015) were collected using field processing methods which included the hand removal of coarse-grained material greater than approximately 0.5 inches in diameter, and hand mixing of the soil volumes in the field from the 32 grab samples. As documented in Field Modification #4, field processing by Roux and Hydrometrics was discontinued at the request of USEPA since the field processing method did not include drying and breaking up soil aggregates and/or sieving as specified in the Interstate Technology and Regulatory Council (ITRC) incremental sampling methodology guidance and as would be done in the lab processing of incremental soil samples (ITRC, 2012a). Three of the initial DUs were re-sampled to allow for a comparison of the results from the two

methods. After the results were considered, it was determined that the remaining 12 DUs would be re-sampled as part of the Phase II Site Characterization effort.

A single replicate was collected from most of the grid cells in the Operational Area. However, three replicates were collected from both the 0 to 0.5 ft and the 0.5 to 2 ft soil intervals from four DUs (i.e., 10 percent of the DUs; CFISS-001, -004, -011, and -015) during the Phase II investigation. Based on the results of the sampling, an estimate of variability from replicate sampling was established for the remaining DUs. An evaluation of the relative standard deviation (RSD) was performed on triplicate results where all three results were detections. The calculation indicated that most analytes had an RSD of less than 30 percent between parent and replicate samples. SVOCs, specifically PAHs, had the greatest frequency of greater than 30 percent RSD between parent and replicate samples. The parent and replicate samples from the shallow incremental soil sampling (ISS) sample CFISS-004 had the greatest range of variability, with SVOC RSD values between 58 percent and 144 percent. It should be noted that the Phase II SAP (Roux, 2018a) denotes an acceptance criterion of 50 percent relative percent difference (RPD) for parent and field duplicate soil samples. Duplicate soil samples are typically expected to be more variable than results from replicate water samples due to the physical and chemical heterogeneity of the soil matrix.

The results of triplicate ISS results were consolidated into a single concentration using the updated ITRC 95 percent UCL_{mean} calculator (ITRC, 2012b), as described in the wildlife ingestion BERA work plan interim deliverable (**Appendix A2**). An adjustment was made to detected constituents in the 39 DUs where single incremental samples were collected based on the variability observed for that constituent within the DUs where triplicate sampling was performed. The RSDs calculated and presented in the Phase II DSR (Roux, 2019) for DUs with triplicate incremental samples were used to estimate the potential variance associated with single incremental sample results. The arithmetic mean of RSDs for each constituent and sampling interval combination was used as the adjustment factor for the 39 DUs lacking replicate samples. This adjustment factor was used to calculate the potential range for each non-replicated DU in each depth interval as follows:

RSD-adjusted EPC = [single ISS result] x (1 ± (mean percent RSD/100)).

Additional information regarding how the ISS data were managed and evaluated is provided in **Section 5.3.1**.

4.1.1.2 Chromium Speciation

In an effort to reduce uncertainty in the risk assessment results with respect to chromium in soil, CFAC developed a site-specific ratio of hexavalent chromium [Cr(VI)] to trivalent chromium [Cr(III)] by collecting soil samples that were analyzed for both total chromium and Cr(VI) (Roux, 2019). Twenty soil samples within the depth of ecological exposure (0 to 2 ft-bgs) were analyzed for both Cr(VI) and total chromium. Cr(VI) was detected in only 3 of the 20 samples and comprised a maximum of 3.96 percent of the total chromium in the samples where it was detected. To determine the representative ratio of Cr(VI) to Cr(III) in soil at the Site, the Cr(III) concentration for each of the samples analyzed for Cr(VI) was calculated as the difference in concentration between total chromium concentration and the Cr(VI) concentration. For non-detect Cr(VI) concentrations at these locations, one-half of the MDL was used for the calculation. The ratio of Cr(VI) to Cr(III) was then calculated for each sample. Cr(III) and Cr(VI) results from soil sample CFSB-290-SO-0-0.5 were excluded from the dataset because both total chromium and Cr(VI) were not detected at this location. The 95 percent UCL_{mean} of all the ratios was then calculated

using ProUCL software (USEPA, 2015b). ProUCL fit the dataset to a lognormal distribution and returned a 95 percent UCL_{mean} ratio of 0.0198 based on the H-statistic method. To be conservative and to follow suggestions from the ProUCL output form, the lognormal distribution result was rejected, and instead, the nonparametric 95 percent UCL_{mean} ratio of 0.0275 was adopted as the representative ratio.

Concentrations of Cr(III) and Cr(VI) were then estimated for the remaining samples for which only total chromium was analyzed, using the above-calculated ratio of Cr(VI) to Cr(III), *r*, the Total Chromium concentration, *Cr(T)*, and the following equations. The raw dataset and calculations are provided in the Phase II DSR (Roux, 2019):

$$[Cr(III)] = \frac{1}{1+r} * Cr(T)$$

$$[Cr(VI)] = r * [Cr(III)]$$

Both the measured total chromium results as well as the estimated Cr(III) and Cr(VI) concentrations based on the above ratio are presented in the soil data tables for each exposure area.

4.1.1.3 Dioxin and Furan Compounds

Concentrations of dioxin and furan congeners were treated according to procedures provided by USEPA and the World Health Organization (WHO) (Van den Berg et al, 1998, 2006; USEPA, 2008b, 2010) and validated according to the appropriate National Functional Guidelines (USEPA, 2016). PCDDs and PCDFs consist of a family of approximately 75 and 135 congeners, respectively. For dioxin and furan congener data, results were converted to 2,3,7,8-tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD) toxicity equivalent quotient (TEQ) values using toxicity equivalent factors (TEFs) specific to wildlife from the World Health Organization (Van den Berg et al., 1998) and Van den Berg et al. (2006) for avian and mammalian receptor guilds, respectively. Three scenarios were calculated for non-detected congeners to bracket the range of potential concentrations present in soil. The three values assigned to results that were qualified as non-detected were 0, one-half the MDL, and the MDL. The MDL represents the lower limit of concentrations detectable by the analytical method. Therefore, any concentrations above the MDL are typically reported as estimated values and are recorded as J-qualified concentrations by the laboratory, which are considered usable results for risk assessment. Thus, the MDL represents a conservative upper limit for the potential concentration of dioxin in a sample reported as a non-detected result.

In some cases, dioxin and furan congener results that had a reported laboratory value were flagged with a laboratory qualifier “B” (indicating blank contamination) and a validation qualifier of “U” (indicating that the influence of the blank contamination compromised the confidence of determining if the constituent was present in the sample at all). In such cases, the estimated concentration reported by the laboratory was conservatively used as the surrogate value for the non-detected result rather than the MDL. All reported and surrogate values were then multiplied by the appropriate bird or mammal TEF, and the TEF-adjusted concentrations were then summed to develop the sample 2,3,7,8-TCDD TEQ concentration (USEPA, 2005c).

4.1.1.4 Soil Evaluation in Transitional Exposure Areas

As described in the BERA Work Plan (EHS Support, 2018), soil and sediment in the four transitional areas (i.e., the North Percolation Pond Area, South Percolation Pond Area, Cedar Creek Overflow Ditch, and

Northern Surface Water Feature) were combined and evaluated as both soil and sediment in order to be protective of ecological receptors that may utilize the sites during dry and wet conditions, respectively. For the soil evaluation in these areas, the soil samples (0 to 2 ft-bgs) and sediment samples were combined to form the soil dataset used to evaluate terrestrial exposure scenarios.

4.1.1.5 PAHs

As described in **Section 3.3.7**, PAHs in terrestrial and aquatic environments have similar modes of toxicity on ecological receptors. Toxicity associated with exposure to PAHs in terrestrial environments is typically considered to be additive among LMW PAHs and HMW PAHs (USEPA, 2007a). LMW PAHs are composed of fewer than four aromatic rings and HMW PAHs are composed of four or more rings. In this BERA investigation, LMW PAHs consisted of acenaphthene, acenaphthylene, anthracene, fluoranthene, fluorene, naphthalene, phenanthrene, and 2-mehtylnaphthalene. HMW PAHs consisted of benzo(a)anthracene), benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, indeno(1,2,3-cd)pyrene, and pyrene. Concentrations of LMW and HMW constituents were summed in the COPEC screening steps and compared to LMW- and HMW-specific ESVs.

PAHs in some soil samples (e.g., in the North Percolation Pond Area) were analyzed using two laboratory analytical methods, 8270D and 8270D-SIM (selected ion monitoring [SIM]). The latter method includes an analysis of additional alkylated compounds that are lacking in the 8270D method, and was intended to enable the calculation of equilibrium partitioning sediment benchmark toxic units (ESBTUs) in the COPEC refinement step (**Section 4.4.1**) based on the full list of 34 PAH compounds (it is noted that these soil samples are in a transitional exposure area, and as such, are evaluated as both soil and sediment in the BERA). For these samples that were analyzed by both methods, the 8270D SIM PAH test was more sensitive (i.e., had lower reporting limits) and were used preferentially over the 8270D method for compounds detected using both methods.

4.1.2 Surface Water

Surface water datasets used in the BERA were comprised of the results of analyses of surface water samples collected over multiple events and hydrologic conditions:

- Phase I Sampling Events:
  - High-Water: June 2016 (Select surface water bodies)
  - Low-Water: September 2016 (Phase I, Round 1)
  - Low-Water: December 2016 (Phase I, Round 2)
  - High-Water: March-April 2017 (Phase I, Round 3)
  - High-Water: June 2017 (Phase I, Round 4)
  - Low-Water: October-November 2017 (Supplemental South Percolation Pond field activities)
- Phase II Sampling Events:
  - High-Water: June 2018 (Phase II, Round 1)
  - Low-Water: October 2018 (Phase II, Round 2)

A description of the phased surface water sampling program is presented below with an evaluation of the sampling events that captured the potential variability in exposure conditions due to temporal variability in surface water hydrology.

4.1.2.1 Phased Surface Water Sampling Program

Phase I surface water samples were collected from site surface water features that were observed to contain water during the Phase I Site Characterization Program. From June 6, 2016 to June 7, 2016, 10 surface water samples were collected from selected surface water bodies that were anticipated to dry-out over the summer months. These locations included the three locations in the South Percolation Ponds, the five locations in the Cedar Creek Reservoir Overflow Ditch, and the two locations in the northern area of the Site where surface water was observed (referred to as the Northern Surface Water Feature on **Figure 2-2**). Surface water was not present within the North Percolation Ponds (North-West and North-East ponds); therefore, surface water samples were not collected from these locations.

From August 29, 2016 to September 16, 2016, 12 surface water samples were collected from within the Flathead River and Cedar Creek during low water conditions. These locations were determined to be wet throughout the entire year. Similar to the June sampling event, surface water samples were not collected within the North Percolation Ponds (North-West and North-East ponds) due to an absence of surface water.

An additional Phase I round of low-water surface water sampling was conducted in December 2016. Phase I high-water sampling rounds were conducted in March-April 2017 and June 2017. In October-November 2017, additional surface water samples were collected in the South Percolation Ponds and Flathead Riparian Area Channel as part of supplemental field activities for the South Percolation Pond Area (Roux, 2017a and 2019).

Phase I surface water samples were analyzed for:

- Total recoverable and one round of dissolved TAL metals (including major cations Ca, Mg, Na, K) via USEPA Methods 200.2 / 200.7 / 200.8 / 245.2 / 6010C / 6020A / 7470A
- Total cyanide via USEPA Method 335.4
- General chemistry including fluoride via USEPA method 300, alkalinity via method SM2023B, and hardness via USEPA method 200.7
- Nutrients including chloride and sulfate via USEPA method 300.0, nitrate and nitrite as N via USEPA method 353.2, ammonia nitrogen via USEPA method 350.1 / 350.3, and orthophosphate as P via USEPA method 365.1
- Total dissolved solids (TDS) and total suspended solids (TSS) via methods SM 2540C/D

In addition to the above analyses, biotic ligand model (BLM) parameters data, including temperature and pH, were also collected. Additional BLM parameters, including dissolved organic carbon and sulfide, were not analyzed in this evaluation but were analyzed during the fourth round of Phase I sampling completed in June 2017.

A Phase II high-water sampling event was performed in June 2018, and a low-water sampling event was performed in October 2018 to assess the temporal variability of surface water quality at the Site. Surface water samples were collected as grab samples from within the Site feature to a maximum depth of approximately 2 feet. Surface water samples were analyzed for:

- Total TAL metals via USEPA Methods 6020A / 7470A
- Dissolved TAL metals via USEPA Methods 6020A / 7470A
- Total cyanide via USEPA Method 335.4
- Free cyanide via USEPA Method 9016

- General chemistry including fluoride via USEPA Method 300, alkalinity via USEPA Method 2320B, and total hardness via USEPA Method 2340C
- Nutrients including total chloride and dissolved sulfate via USEPA Method 300.0, nitrate and nitrite as N via USEPA Method 353.2, ammonia nitrogen via USEPA Method 350.1, sulfide via USEPA Method 4500S2F, and orthophosphate as P via USEPA Method 9056A
- Total cyanide via USEPA Method 335.4, dissolved cyanide via USEPA Method 335.4, and free cyanide via USEPA Method 9016 (four opportunity samples in Cedar Creek TCL SVOCs via USEPA Method 8270 LL)
- Alkylated PAHs via USEPA Method 8270D-SIM (select samples in the Backwater Seep Sampling Area, Riparian Area, and Flathead River)

All surface water samples submitted for analysis of dissolved parameters were field filtered using a standard 0.45-micron filter.

4.1.2.2 Temporal Variability in Surface Water Hydrology

Further evaluation of the long-term discharge record for the Flathead River (USGS Gage 12363000) was conducted to determine how the daily flow conditions at the time of each sampling event compared to flow statistics computed with the entire period of daily records (June 1, 1922 to February 4, 2019). This assessment was carried out to identify how discharge conditions in the Flathead River during Phase I and Phase II surface water sampling events compared to annual flow percentiles, which were calculated for the entire population. Daily discharge of the Flathead River from January 2016 to February 2018 is illustrated in **Figure 3-5**. Sampling was conducted predominately during low flow periods representing the 20^{th} – 50^{th} percentiles of flow (Q_{20}-Q_{50}). June sampling events in 2016, 2017, and 2018 reflect periods of high discharge associated with the spring freshet. Discharge during these events was typically greater than the 85^{th} percentile. The combined evaluation of mean monthly statistics for the last 10 years and flow statistics computed from period of record for the Flathead River demonstrate that aqueous phase sampling conducted during Phase I and Phase II investigations comprise a wide range of hydrologic conditions that effectively capture the temporal variability of discharge.

4.1.3 Sediment

Phase I data collection occurred on August 29, 2016 and from September 6 to 9, 2016. Sediment samples were collected from the same locations as surface water samples immediately following the collection of surface water samples at each location. Sediment sampling also included two locations within the North-East and North-West Percolation Ponds where surface water samples were not collected due to the absence of surface water within those features. Sediment samples were collected when river stage levels were low such that the Flathead River would most likely be acting as a gaining stream. Sediment sample locations for transitional and aquatic exposure areas are shown on **Figure 4-9** through **Figure 4-14**.

Gravel and larger sized grains were removed from the sample by passing the grab sediment sample through a size 10 sieve prior to packaging and shipment for laboratory analysis. Sediment samples were analyzed with the same analytical methods as the soils described in **Section 4.1.1** , including grain size analysis and total organic carbon.

Phase II sediment samples were collected during both the high-water event in June 2018 and the low-water sampling event in October 2018. Sediment samples were collected from surface water sample locations previously sampled during Phase I and Supplemental South Pond Assessment, and additional locations added for the Phase II as described in the Phase II SAP (Roux, 2018a). Sediment samples were analyzed for:

- TCL SVOCs via USEPA Method 8270 LL
- TAL metals via USEPA Method 6020A / 7471B
- Total cyanide via USEPA Method 9014
- Fluoride via USEPA Method 9056A

In addition to the above described analyses, select sediment samples located in the Backwater Seep Sampling Area, Riparian Area, South Percolation Ponds, and the Flathead River were also analyzed for the following additional analytes:

- AVS-SEM via USEPA-821-R-100
- Alkylated PAHs via USEPA Method 8270D (CFSDP-005, 026, 027, 028, 029, and 035)

4.1.3.1 PAHs

The potential effects of PAH-induced narcosis on benthic invertebrate communities can include decreased abundance, diversity, and growth (Environment Canada, 1999). The direct contact toxicity of PAHs is additive. Total PAH (tPAH) values were established for sediment samples based on the summed concentrations of the following compounds that comprise the toxic effect level (TEL) screening value that was used in the initial COPEC screening evaluation: acenaphthene, acenaphthylene, anthracene, benzo(k)fluoranthene, benzo(b)fluorene, benzo(a)anthracene, benzo(a)pyrene, benzo(g,h,i)perylene, chrysene, dibenzo(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, and pyrene.

Similar to the soil samples in the North Percolation Pond Area (**Section 4.1.1.5**), PAHs in some sediment samples in the Flathead River Riparian Area and the Flathead River Area were analyzed using two laboratory analytical methods, 8270D and 8270D-SIM, which includes an analysis of additional alkylated compounds that are lacking in the 8270D method. These data were addressed using the same approach described in **Section 4.1.1.5** for soils.

4.1.3.2 Sediment Evaluation in Transitional Exposure Areas

As described in the BERA Work Plan (EHS Support, 2018), soil and sediment in the four transitional areas (i.e., the North Percolation Pond Area, South Percolation Pond Area, Cedar Creek Reservoir Overflow Ditch, and Northern Surface Water Feature) were combined and evaluated as both soil and sediment in order to be protective of ecological receptors that may utilize the sites during dry and wet conditions, respectively. For the sediment evaluation in these areas, soil samples from the shallow soil interval (0 to 0.5 ft-bgs) and sediment samples were combined to form the sediment dataset used to evaluate aquatic or semi-aquatic exposure scenarios that may occur when the areas are inundated.

4.2 BERA Screening-Level COPEC Criteria

In this step of the screening-level evaluation, exposure to stressors and the relationship between stressor concentrations and ecological effects are evaluated. Maximum concentrations in environmental

media (soil, surface water, and sediment) are the EPCs that are compared to corresponding media-specific conservative effects benchmarks. For each exposure area, constituents were selected for further analysis as COPECs if the maximum detected concentration exceeded an ESV. Constituents that were not detected were not retained as COPECs. However, if one-half the MDL for a non-detected constituent exceeded the most conservative screening level, that constituent was retained for further evaluation in the COPEC refinement (**Section 4.4**). Constituents lacking ESVs were not removed as COPECs at the initial screening stage but were carried forward for evaluation in the COPEC refinement. Constituents that also lacked refined ESVs were discussed in the COPEC refinement uncertainty section.

Consistent with the original Site SLERA (Roux, 2017b), the ESVs for this screening-level COPEC identification step were gathered from the following sources, as detailed in the RI/FS Work Plan (Roux, 2015a) or otherwise requested by USEPA, for each media type:

- Soil
  - USEPA Ecological Soil Screening Levels (USEPA, 2005b)
  - Los Alamos National Laboratory (LANL) ECORISK Database (LANL, 2017)
  - *Toxicological Benchmarks for Screening Contaminants of Potential Concern for Effects on Soil and Litter Invertebrates* (Efroymson et al., 1997a)
  - *Toxicological Benchmarks for Screening Contaminants of Potential Concern for Effects on Terrestrial Plants* (Efroymson et al., 1997b)
  - Region 5 Resource Conservation and Recovery Act (RCRA) Ecological Screening Levels (USEPA, 2003b)
- Surface Water:
  - USEPA National Recommended Water Quality Criteria (USEPA, 2019)
  - Montana Department of Environmental Quality (MDEQ) Circular DEQ-7 (MDEQ, 2017)
  - *Toxicological Benchmarks for Screening Potential Contaminants of Concern for Effects on Aquatic Biota* (Suter and Tsao, 1996)
  - USEPA Region 3 Freshwater Screening Benchmark (USEPA, 2006a)
  - Canadian Water Quality Guidelines, Summary Table (CCME, 2008)
- Sediment:
  - Development and Evaluation of Consensus-Based Sediment Quality Guidelines for Freshwater Ecosystems (MacDonald et al., 2000)
  - USEPA Region 3 Freshwater Sediment Screening Benchmarks (USEPA, 2006b)
  - *Calculation and evaluation of sediment effect concentrations for the amphipod Hyalella azteca and the midge Chironomus riparius* (Ingersoll et al., 1996)
  - Region 5 RCRA Ecological Screening Levels (USEPA, 2003b)

The minimum ESV from these sources was selected as the benchmark criterion for the selection of screening-level COPECs. A comprehensive summary of all the soil, surface water, and sediment ESVs used during this evaluation are provided in **Appendix B**. Because chromium speciation data were used to estimate relative concentrations of Cr(III) and Cr(VI) in all soil samples (**Section 4.1.1.2**), soil ESVs based on trivalent chromium were used for comparison to total and estimated Cr(III) concentrations, and soil ESVs based on hexavalent chromium were used for comparison to Cr(VI) concentrations.

Surface water ESVs are based upon chronic toxicity values and applied based on the filtered (dissolved) or unfiltered (total) fraction in accordance with the basis of the minimum ESV selected for each constituent. ESVs were based on dissolved criteria for metals with dissolved criteria promulgated as National Recommended Water Quality Criteria (NRWQC); ESVs were also evaluated based on total

criteria for metals, except for aluminum, consistent criteria promulgated in MDEQ Circular 7 (MDEQ, 2017). Hardness- or pH- dependent surface water ESVs shown in **Appendix B** for ammonia, cadmium, lead, nickel, and zinc were calculated using sample-specific hardness values, consistent with the BERA Work Plan. The resulting calculations for these sample-specific adjustments are presented in **Appendix D.**

As specified in the SLERA, when evaluating each pathway, maximum constituent concentrations measured in soil, surface water, and sediment within each exposure area were compared to the lowest identified ESV obtained from the above sources. By using maximum concentrations in the environmental media (soil, surface water, and sediment) and the lowest screening benchmarks, the initial COPEC screening evaluation is designed to minimize chances of eliminating a COPEC from further consideration when it may pose an actual ecological risk. Thus, the resulting risk calculation is expected to be an overestimate of actual risk (USEPA, 1997).

If the maximum concentration of a constituent exceeded the most conservative ESV, the COPEC was retained for further evaluation in the ecological risk assessment process. If the maximum concentration was less than the ESV, this indicates that adverse effects are not likely, and the analyte can be eliminated from further investigations.

4.3 Screening-Level Selection of COPECs

The full compilation of screening-level selection tables for all exposure areas and media are presented in **Appendix B**. A summary table of the results is presented in **Table 4-14** for soil and sediment, and **Table 4-15** for surface water. The results of the initial screening-level selection of COPECs for all exposure areas are discussed in the following subsections. Constituents were identified as screening-level COPECs if their maximum detected concentration exceeded the minimum screening ESV, or if no ESV was available.

4.3.1 Terrestrial Exposure Areas

The results of the screening-level COPEC selection process are described below for soil in the seven terrestrial exposure areas at the Site.

4.3.1.1 Main Plant Area

For the Main Plant Area, 25 inorganics (including metals, other inorganic parameters, and essential nutrients), 14 individual PAH compounds, both LMW and HMW PAH categories, 7 non-PAH SVOCs, 6 VOCs, dioxins, and 1 PCB were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.1.2 Central Landfills Area

For the Central Landfills Area, 25 inorganics (including metals, other inorganic parameters, and essential nutrients), 15 individual PAH compounds, both LMW and HMW PAH categories, 8 non-PAH SVOCs, 6 VOCs, dioxins, and 1 PCB were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.1.3 Industrial Landfill Area

For the Industrial Landfill Area, 25 inorganics (including metals, other inorganic parameters, and essential nutrients), 10 individual PAH compounds, and both LMW and HMW PAH categories were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.1.4 Eastern Undeveloped Area

For the Eastern Undeveloped Area, 21 inorganics (including metals, other inorganic parameters, and essential nutrients), 2 individual PAH compounds, HMW PAHs, and 4 non-PAH SVOCs were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.1.5 North-Central Undeveloped Area

For the North-Central Undeveloped Area, 20 inorganics (including metals, other inorganic parameters, and essential nutrients), HMW PAHs, 2 non-PAH SVOCs, and 1 VOC were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.1.6 Western Undeveloped Area

For the Western Undeveloped Area, 22 inorganics (including metals, other inorganic parameters, and essential nutrients), HMW PAHs, 3 non-PAH SVOCs, 4 VOCs, and dioxins were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.1.7 Flathead River Riparian Area

For the Flathead River Riparian Area, 17 inorganics (including metals, other inorganic parameters, and essential nutrients), 1 individual PAH compound, HMW PAHs, 3 non-PAH SVOCs, and 5 VOCs were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.2 Incremental Soil Sampling Area

For the Incremental Soil Sampling Area, the initial COPEC selection step was performed using Operational Area data comprised of the three scenarios described in **Section 4.1.1.1**. This data set was comprised of the UCL concentrations from the DUs with triplicate ISS samples, plus 1.) results from non-triplicate DUs adjusted high using the RSD adjustment factor, 2.) the original measured concentrations in the non-triplicate DUs, and 3.) results from non-triplicate DUs adjusted low using the RSD adjustment factor. Only the high-adjusted dataset was used to select screening-level COPECs in the ISS area soil. 26 inorganics (including metals, other inorganic parameters, and essential nutrients), 16 individual PAH compounds, LMW and HMW PAHs, 8 non-PAH SVOCs, and 2 PCBs were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.3 Transitional Exposure Areas

The results of the screening-level COPEC selection process are described below for soil and sediment in the four transitional exposure areas at the Site.

4.3.3.1 North Percolation Pond Area

4.3.3.1.1 Soil

For the North Percolation Pond Area, 26 inorganics (including metals, other inorganic parameters, and essential nutrients), 16 individual PAH compounds, both LMW and HMW PAH categories, 4 non-PAH SVOCs, and 6 VOCs were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.3.1.2 Surface Water

For the North Percolation Pond Area, 19 inorganic constituents (including both total and filtered fractions) and 9 PAHs were identified as screening-level COPECs in surface water. These constituents were carried forward for COPEC refinement, as described in **Section 4.4**.

4.3.3.1.3 Sediment

For the North Percolation Pond Area, 23 inorganics (including metals, other inorganic parameters, and essential nutrients), 17 individual PAH compounds, Total PAHs, and 3 non-PAH SVOCs were identified as screening-level COPECs in sediment. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.3.2 South Percolation Pond Area

4.3.3.2.1 Soil

For the South Percolation Pond Area, 24 inorganics (including metals, other inorganic parameters, and essential nutrients), 2 individual PAH compounds, HMW PAHs, 5 non-PAH SVOCs, and 5 VOCs were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.3.2.2 Surface Water

For the South Percolation Pond Area, 26 inorganic constituents (including both total and filtered fractions) and 3 PAHs were identified as screening-level COPECs in surface water. These constituents were carried forward for COPEC refinement, as described in **Section 4.4**.

4.3.3.2.3 Sediment

For the South Percolation Pond Area, 19 inorganics (including metals, other inorganic parameters, and essential nutrients), 13 individual PAH compounds, Total PAHs, 5 non-PAH SVOCs, and 5 VOCs were

identified as screening-level COPECs in sediment. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.3.3 Cedar Creek Overflow Ditch

4.3.3.3.1 Soil

For the Cedar Creek Reservoir Overflow Ditch Area, 18 inorganics (including metals, other inorganic parameters, and essential nutrients), 1 individual PAH compound, HMW PAHs, and 3 non-PAH SVOCs were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.3.3.2 Surface Water

For the Cedar Creek Reservoir Overflow Ditch Area, 10 inorganic constituents (including both total and filtered fractions) were identified as screening-level COPECs in surface water. These constituents were carried forward for COPEC refinement, as described in **Section 4.4**.

4.3.3.3.3 Sediment

For the Cedar Creek Reservoir Overflow Ditch Area, 13 inorganics (including metals, other inorganic parameters, and essential nutrients), 14 individual PAH compounds, Total PAHs, and 3 non-PAH SVOCs were identified as screening-level COPECs in sediment. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.3.4 Northern Surface Water Feature

4.3.3.4.1 Soil

For the Northern Surface Water Feature Area, 18 inorganics (including metals, other inorganic parameters, and essential nutrients) and 1 non-PAH SVOC were identified as screening-level COPECs in soil. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.3.4.2 Surface Water

For the Northern Surface Water Feature Area, 10 inorganic constituents (including both total and filtered fractions) were identified as screening-level COPECs in surface water. These constituents were carried forward for COPEC refinement, as described in **Section 4.4**.

4.3.3.4.3 Sediment

For the Northern Surface Water Feature Area, 14 inorganics (including metals, other inorganic parameters, and essential nutrients), 10 individual PAH compounds, Total PAHs, and 4 non-PAH SVOCs were identified as screening-level COPECs in sediment. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.4 Aquatic Exposure Areas

The results of the screening-level COPEC selection process are described below for surface water and sediment in the two aquatic exposure areas at the Site.

4.3.4.1 Flathead River

4.3.4.1.1 Surface Water

For the Flathead River, 16 inorganic constituents (including both total and filtered fractions), 11 PAHs, and 2 non-PAH SVOCs were identified as screening-level COPECs in surface water. These constituents were carried forward for COPEC refinement, as described in **Section 4.4**.

4.3.4.1.2 Sediment

For the Flathead River, 8 inorganics (including metals, other inorganic parameters, and essential nutrients), 14 individual PAH compounds, Total PAHs, 4 non-PAH SVOCs, and 5 VOCs were identified as screening-level COPECs in sediment. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.3.4.2 Cedar Creek

4.3.4.2.1 Surface Water

For Cedar Creek, 10 inorganic constituents (including both total and filtered fractions) were identified as screening-level COPECs in surface water. These constituents were carried forward for COPEC refinement, as described in **Section 4.4**.

4.3.4.2.2 Sediment

For Cedar Creek, 9 inorganics (including metals, other inorganic parameters, and essential nutrients), 12 individual PAH compounds, Total PAHs, and 2 non-PAH SVOCs were identified as screening-level COPECs in sediment. These constituents were carried forward to the refinement COPEC selection step described in **Section 4.4**.

4.4 Refined COPEC Screening Process

Following the initial selection of screening-level COPECs, a refined COPEC screening process was conducted to preliminarily identify focal COPECs that may influence the BERA. The refined COPEC screening process considers alternative ESVs and other criteria for COPECs identified in the conservative SLERA screening process. A fundamental step in the baseline problem formulation is the refinement of COPECs to identify those constituents that are most likely to drive risk management decision-making for the Site. The intent of the refinement step is to focus and streamline the overall ERAGS process. COPEC refinement in the BERA problem formulation is consistent with USEPA *The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments* (USEPA, 2001a). Specific elements of COPEC refinement include consideration of the following:

- Use of refined ESVs: Alternative ESVs that are protective of chronic exposure but represent a broader range of protective NOEC endpoints are considered to provide context for the potential ecological risk associated with COPECs identified in the initial screening step, and to focus evaluation of COPECs in the BERA.
- Background concentrations: COPECs in exposure areas at concentrations that are not significantly different from background concentrations may represent regional conditions that are not related to site activities or are not likely to drive risk in the BERA.
- Frequency of detection: COPECs that are infrequently detected (less than 5 percent) are not likely to ultimately drive risk management decisions in the BERA process. The magnitude of exceedance of ESVs and BTVs was considered as part of the refinement of infrequently detected COPECs.
- Dietary considerations: COPECs that serve as essential nutrients (e.g., calcium, iron, magnesium, sodium, and potassium) typically pose little threat to ecological receptors when present in concentrations that allow them to function as nutrients. As described in **Section 4.4.4** however, calcium received special consideration due to its potential presence at elevated concentrations due to its generation in historical waste streams at the Site.

Each of these criteria are discussed in greater detail in the following sections. Additionally, COPECs retained because they lacked ESVs, or with MDLs exceeding conservative ESVs are re-evaluated in the refined COPEC screening uncertainty section as part of the BERA Problem Formulation.

4.4.1 Refined ESVs

As discussed in **Section 3.2**, the conservative exposure scenario evaluated in the SLERA (maximum exposure concentrations and minimum ESVs) and incorporated into the screening-level COPEC selection in the BERA problem formulation minimizes the potential for COPECs to be dismissed from the screening process prematurely, but does not provide a basis for assessing the potential for adverse effects to occur. Alternative ESVs are used in the COPEC refinement process to be protective of chronic exposure to ecological receptor groups, but also represent a broader range of NOECs than the minimum ESVs used in the conservative initial screening step.

A summary of preliminary ESVs used for the initial BERA screening-level COPEC identification is presented in **Appendix B**. Additional documentation and description of the refined ESVs used for the BERA COPEC refinement is presented in **Table A-1** (soil and sediment) and **Table A-2** (surface water and ground water) in the ESV Interim Deliverable presented in **Appendix A1**. This interim deliverable was prepared for USEPA review to support the selection of revised ESVs from a range of NOECs identified in literature sources. The refined ESVs are used in the COPEC refinement step of the BERA Problem Formulation to re-screen data from each exposure area and exposure medium based on the combined Phase I and Phase II Site Characterization datasets.

For the BERA COPEC refinement, Phase I and Phase II data were grouped by exposure medium, and maximum concentrations were compared to alternative ESVs. For soil, COPEC refinement included comparison of surface (0-0.5 ft) and shallow (0.5-2 ft) soil data from terrestrial and transitional exposure areas, as well as sediment data from transitional exposure areas (as described in **Section 4**) to refined soil ESVs. For surface water, COPEC refinement included comparison of surface water data from aquatic and transitional exposure areas to refined ESVs based on USEPA NRWQC or MDEQ chronic surface water quality for the protection of aquatic life. For sediment, COPEC refinement included comparison of

sediment data from aquatic exposure areas, and a combination of surficial (0 to 0.5 ft) soil and sediment from transitional exposure areas (as described in **Section 4.1.3.2**) to refined sediment ESVs. The following sections summarize the refined COPEC screening process. A complete description of the ESVs used for the refined COPEC screen is presented in the refined ESVs interim deliverable presented in **Appendix A1**. The raw data used to perform the BERA is presented in the Phase II DSR (Roux, 2019).

4.4.1.1 Refined Soil ESVs

Refined soil ESVs were derived based on peer-reviewed, multi-trophic level soil screening criteria. The derivation of refined soil screening criteria was based on the USEPA approach for deriving ecological soil screening levels (Eco-SSLs). Eco-SSLs were derived as risk-based soil screening levels through a peer review process for the protection of multiple terrestrial receptor categories (USEPA, 2005b):

- Terrestrial plants
- Soil invertebrates
- Birds
- Mammals

Eco-SSLs are intended for use in the screening process to identify constituents that are not of potential ecological concern and do not need to be considered in the BERA (USEPA, 2005b). Eco-SSLs are considered to be protective of terrestrial ecosystems, including rare, endangered, and threatened species that may be present (USEPA, 2005b). Per Eco-SSL guidance, toxicity of aluminum and iron to terrestrial biota exhibits little correlation to detected concentrations in soil. Rather, the acidity of the soil was found to be a much more reliable indicator of toxic effects. As such, the guidance recommends replacing a numeric screening value associated with constituent toxicity with the measured soil pH. Soils with pH greater than 5.5 for aluminum and 5 for iron are considered to pose little to no risk to ecological receptors. The laboratory-measured pH from 36 soil samples collected across the Site ranged from 7.4 to 9. Therefore, aluminum and iron were excluded as COPECs in soil at all exposure areas.

To supplement established Eco-SSL criteria, endpoints from the multiple terrestrial receptor categories included in the Eco-SSL approach were compiled from the LANL ECORISK Database (Release 4.1; LANL, 2017). The LANL ECORISK Database presents benchmarks that were developed using an approach similar to the derivation of Eco-SSLs, i.e., the guidance selected geometric mean concentrations of NOEC endpoints as the screening criteria for multiple terrestrial receptor foraging guilds, or generic receptor groups, within a specific medium. The minimum of the available LANL and Eco-SSL values for multiple terrestrial receptor foraging guilds or groups was used in the BERA as the refined soil ESV for that constituent to provide for the protection of each receptor group. In the absence of sufficient data to refine soil ESVs based on the Eco-SSL approach, the conservative minimum ESV used in the SLERA was retained.

Avian and mammalian exposures to the mixture of 17 dioxin and furan compounds analyzed in surficial soil samples were evaluated relative to the toxicity of 2,3,7,8-TCDD using TEFs developed for birds and mammals by the WHO (Van den Berg et al., 2006; Van den Berg et al., 1998; USEPA, 2008b). For dioxin and furan screening, measured concentrations of the 17 dioxin and furan compounds in surface soil samples were multiplied by compound specific TEFs to calculate toxicity equivalence concentrations (TECs) for each compound. The summed TECs for each sample were compared to soil concentrations protective of avian and mammalian exposure to 2,3,7,8-TCDD. As discussed in **Section 4.1.1.4**, dioxin

and furan concentrations that were below the detection limit were estimated as 0, one-half the MDL, and the MDL. TEC calculations for dioxin and furan samples are provided in **Appendix C**.

Terrestrial plant and soil invertebrate exposures to dioxin and furan compounds were not considered in the screening evaluation since it has been demonstrated that a wide variety of invertebrates and plants are insensitive to dioxin and furan exposure relative to birds and mammals (USEPA, 2008b). However, the LANL ECORISK Ecological Screening Level of 5 mg/kg for 2,3,7,8-TCDD is included in the evaluation of soil-dwelling invertebrate direct contact exposure to dioxin and furan compounds.

In the absence of sufficient data to refine soil ESVs, the conservative minimum ESVs used in the SLERA were retained.

4.4.1.2 Refined Surface Water ESVs

Refined ESVs for surface water were preferentially based on USEPA NRWQC or MDEQ chronic surface water quality for the protection of aquatic life. Chronic aquatic life surface water criteria are derived for the protection of 95 percent of aquatic species. Therefore, these criteria are considered adequately protective to identify COPEC concentrations in surface water that have the potential to result in adverse ecological effects and warrant additional evaluation in the BERA. In the absence of NRWQC or MDEQ criteria, refined ESVs were selected from the sources listed in **Section 4.2** that are protective of chronic exposure.

Refined ESVs were applied to sample results corresponding to the aqueous toxicity data used to establish the chronic aquatic life surface water criteria. For many metals, NRWQC chronic surface water quality criteria are based on exposure to the dissolved phase. For these COPECs, refined ESVs were applied to filtered surface water sample results[2], which operationally represent the dissolved COPEC phase in the sample. MDEQ criteria for metals, except for aluminum, are based on the total result; therefore, MDEQ criteria were applied to unfiltered surface water sample results. If either phase of metal exceeded refined ESVs, the COPEC was retained for further evaluation in the BERA.

Hardness- or pH- dependent refined ESVs were derived on a sample-specific basis for ammonia, fluoride, cadmium, chromium, lead, nickel, zinc, and pentachlorophenol, consistent with the BERA Work Plan. USEPA NRWQC for copper and aluminum are based on models developed to characterize the bioavailable forms of these metals in surface water based on water quality parameters. The NRWQC for copper is based on the USEPA BLM, which accounts for organic compounds and inorganic ligands in surface water that are known to complex with copper and affect bioavailability and toxicity (USEPA, 2007b). For aluminum, the refined ESV is based on recently promulgated (December 2018) USEPA aquatic life ambient water quality criteria developed using multiple linear regression models to characterize aluminum bioavailability based on pH, hardness, and dissolved organic carbon (DOC; USEPA, 2018). The associated calculations for sample-specific adjustments for refined surface water ESVs are presented in **Appendix D.**

In the absence of sufficient data to refine surface water ESVs based on USEPA NRWQC or MDEQ surface water quality criteria, the conservative minimum ESVs used in the SLERA were retained.

[2] Filtered samples were collected in the fourth round of Phase I sampling and in all Phase II sampling rounds.

4.4.1.3 Refined Sediment ESVs

Refined ESVs for sediment were based primarily on consensus-based criteria and equilibrium partitioning-based criteria for PAHs. Consistent with the approach used for refined soil ESVs, refined sediment ESVs for metal COPECs and select organic COPECs were estimated as the geometric mean of NOEC endpoints following the consensus-based approach (MacDonald et al., 2000).

Refined ESVs for PAHs in sediment were based on USEPA *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures* (USEPA, 2003a). ESBs derived in USEPA (2003a) were used to estimate the potential additive narcotic effects of PAH mixtures in sediment based on theoretical partitioning of PAH compounds between organic carbon and pore water. Exposure to the PAH mixture was evaluated based on the sum of equilibrium partitioning sediment benchmark toxic units (∑ESBTUs) calculated from individual PAH compounds:

$$\sum ESBTU_{FCV,Total} = \sum_{i=1}^{13} \frac{C_{oc,PAHi}}{C_{oc,PAHi,FCVi}} \times UF$$

where:

$\sum ESBTU_{FCV,Total}$ = Sum of ESBTUs for the PAH mixture based on 34 PAH compounds (unitless)

$C_{oc,PAHi}$ = Organic carbon normalized concentration of PAH *i* ($\mu g/g_{oc}$)

$C_{oc,PAHi,FCVi}$ = Organic carbon normalized critical concentration of PAH *i* based on the final chronic value (FCV; $\mu g/g_{oc}$)

UF = Uncertainty factor to estimate the toxicity of total PAHs (based on 34 PAHs – 18 parent and 16 alkylated compounds)

Sediment samples collected in the Phase I and II Site Characterization were analyzed for 13 or 34 PAH compounds included in the USEPA ESB model. For samples analyzed for 13 PAHs compounds, an uncertainty factor of 2.75 was applied to account for the potential toxicity of unmeasured PAHs in the ∑ESBTU calculation (USEPA, 2003a). Some sediment samples in the Flathead River Riparian and Northern Percolation Pond transitional areas, and the Flathead River aquatic exposure area were also analyzed during Phase II for a broader suite of PAHs using the SIM analytical method 8270D SIM. This method analyzes for 34 PAHs (18 parent and 16 alkylated compounds). For these samples, ∑ESBTU values were calculated without the use of an uncertainty factor. Method 8270D SIM data were used preferentially over the non-SIM PAH results, when available. ∑ESBTU values less than or equal to 1.0 are considered acceptable for the protection of benthic invertebrate receptors; values exceeding 1.0 indicate a potential for narcotic effects in benthic receptors (USEPA, 2003a). ∑ESBTU values greater than 10 result in more frequent adverse effects to benthic test organisms.

Several non-PAH nonionic organic constituents were identified as screening-level COPECs in sediment in transitional and aquatic exposure areas, including 3- and 4-methylphenol, 4-chloroaniline, benzaldehyde, bis(2-ethylhexyl)phthalate (BEHP), carbazole, acetophenone, dibenzofuran, and phenol. ESBs for these constituents were developed using the EqP approach described in *Procedures for the*

Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: Compendium of Tier 2 Values for Nonionic Organics (USEPA, 2008a). ESB values represent concentrations of nonionic organic constituents in bulk sediment that, at equilibrium, would result in partitioning to sediment pore water at concentrations equivalent to NOEC water quality benchmarks (WQB_{NOEC}). ESB_{NOEC} values for nonionic constituents were calculated using chronic $WQBs_{NOEC}$ and constituent-specific organic carbon-water partitioning coefficients (K_{oc}):

$$ESB_{NOEC} = (f_{oc} \times K_{oc} \times WQB_{NOEC})$$

where:

ESB_{NOEC} = Equilibrium-partitioning sediment benchmark based on NOEC aqueous toxicity data (microgram per kilogram [µg/kg] dw sediment)

f_{oc} = Fraction of organic carbon in sediment

K_{oc} = Organic carbon-water partitioning coefficient (liter per kilogram [L/kg])

WQB_{NOEC} = Water quality benchmark based on a chronic NOEC (microgram per liter [µg/L])

If available, appropriate WQB_{NOEC} values were identified from the preliminary ESVs for surface water (**Appendix B**). Constituent-specific organic carbon-water partitioning coefficient (K_{oc}) values were calculated as a function of K_{ow}. Constituent-specific values for K_{ow} were obtained from EPA Estimation Programs Interface (EPI) Suite database. K_{oc} values were estimated based on constituent-specific K_{ow} values based on the following relationship (USEPA, 2008a; Di Toro et al, 1991):

$$\log K_{oc} = 0.0028 + 0.983 \times (\log K_{ow})$$

where:

$\log K_{oc}$ = log organic carbon-normalized sediment quality benchmark (L/kg)
$\log K_{ow}$ = log octanol-water partition coefficient (unitless)

Equilibrium partitioning-based benchmark calculations for non-PAH and PAH constituents are presented in **Appendix F** and **Appendix G**, respectively. In the absence of consensus-based or equilibrium partitioning approaches, refined sediment ESVs were selected from the sources listed in **Section 4.2** that are protective of chronic exposure. If sufficient data were not available to refine sediment ESVs, the conservative minimum ESV used in the SLERA was retained.

4.4.2 Background Evaluation

As described in the *Background Investigation Sampling and Analysis Plan* (Roux, 2018b), soil background samples were collected from four nearby terrestrial areas with soil types that match those found at the Site. Surface water and sediment background samples were collected from two aquatic reference areas upgradient of the influence of any potential Site waste streams. Data from these samples were used to calculate general statistics on background constituents, including BTVs that are intended to represent upper-bound background concentrations. The methods and results of these calculations are presented in (Roux, 2019).

Following the procedures outlined in the Background SAP (Roux, 2018b), for exposure areas except the ISS grid (i.e., the Operational Area), UCL_{mean} concentrations for constituents detected in the on-site

ecological exposure areas were compared to the mean background concentration for the constituents derived from the reference area samples as an initial evaluation as to whether the constituent was background-related. The UCL_{mean} concentrations were calculated only for site data obtained from the shallow (0 to 0.5 ft-bgs) soil samples to match the depths of soils collected in the background reference area (Roux, 2018b and 2019). USEPA ProUCL software (version 5.1; USEPA, 2015b) was used to calculate the on-site statistics for comparison to background. Occasionally, ProUCL recommended a UCL_{mean} based on the H-statistic method, which often results in an impractically large UCL value. Based on general recommendations in the ProUCL User's Guide (USEPA, 2015b), an alternate calculated UCL_{mean} (usually the Chebyshev 95 percent UCL_{mean}) was selected for use for that constituent. ProUCL output and summary statistics are presented in **Appendix I.** Because the ISS grid consists of a combination of UCLs calculated for the DUs with triplicate data and single ISS sample data adjusted based on the RSD of the DUs with triplicates (see **Section 4.1.1.1**), developing an Operational Area-wide UCL value to compare against the mean background concentrations is not statistically appropriate, as the concentrations from the individual DUs have varying statistical properties and underlying assumptions. Therefore, comparisons to background concentrations were not used as a criterion for refining COPECs in the Operational Area ISS grid.

Table 4-16 presents the background reference areas that were selected for comparison to the terrestrial, transitional, and aquatic exposure areas. The selection of reference areas for the aquatic exposure areas is straightforward; constituents detected in surface water and sediment in the Flathead River and Cedar Creek aquatic exposure areas were compared with concentrations in the upgradient Flathead River and Cedar Creek reference areas, respectively. For soil, four background reference areas were established (SO#1, SO#2, SO#3, and SO#4) that reflected soil types found on-site. The background dataset for the reference area that had the most similar soil type to the exposure area being investigated was selected for the background comparison in this BERA. The Flathead Valley in the vicinity of the site is comprised of three primary soil types: 1) Glacial Till and Alluvium (soils deposited by glacial activity); 2) Fluvial Deposits and Riverwash (soils deposited by river activity); and 3) Mountainous Land with Glacial Deposits, which is expressed at the surface as Teakettle Mountain (soil interaction between the glacial outwash and bedrock) (Roux, 2018b). Although most ecological exposure areas near the facility were comprised of glacial till and alluvium, the mountainous land will glacial deposits soil type had a minor presence (e.g., less than approximately 10 percent spatial coverage) at a few of the areas. In these cases, the soil reference area that represented the dominant soil type at the exposure area was selected for the background evaluation. In all terrestrial and transitional soil areas, except for the Flathead River Riparian Area and the South Percolation Pond Area, the dominant soil type was influenced by glacial till and alluvium most similar to soil from background reference area SO#1. The Flathead River Riparian Area and the South Percolation Pond Area are both located in soil types dominated by alluvial deposits. Two background reference areas (SO#2 and SO#3) were collected in soil types similar to these two exposure areas. The lower of these two background concentrations was selected as the mean concentration for comparison to the UCL_{mean} of concentrations detected in the Flathead River Riparian Area and the South Percolation Pond Area.

As described in **Section 4.1.1**, soil and sediment samples collected from transitional exposure areas were evaluated both as soil and as sediment to account for protecting the different receptor communities that may use the areas during dry periods and during inundation. The underlying soil type guided the selection of the background soil reference area for the soil comparison, as discussed above. For the sediment comparison, the Cedar Creek Reservoir Overflow Ditch transitional area has an upgradient connection to Cedar Creek; therefore, the Cedar Creek background sediment data were used for the sediment evaluation in this exposure area. The North and South Percolation Ponds and the Northern

Surface Water Feature transitional exposure areas are hydrologically isolated from the two aquatic reference areas in the Flathead River and Cedar Creek. The transitional sediment/soil areas represent process-driven depressions where organic material and fines are likely to have been deposited. Thus, the substrates in these areas have characteristics that make a comparison to background concentrations derived from stream and river systems inappropriate. Therefore, the background soil reference area selected for the soil comparison in these three transitional exposure areas were also used for the sediment comparison.

Surface water in the transitional exposure areas was compared to background reference data from the most appropriate aquatic reference water body based on proximity, overland flow patterns, and regional drainage characteristics. Based on this evaluation, surface water from the North Percolation Pond Area, Cedar Creek Reservoir Overflow Ditch, and the Northern Surface Water Feature were compared to surface water reference data from Cedar Creek. Surface water from the South Percolation Pond Area was compared to surface water reference data from the Flathead River.

Constituents in each exposure area with 95 percent UCL_{mean} concentrations below the mean background concentration were not retained as COPECs (Roux, 2018b). However, constituents excluded as COPECs based on this comparison, with maximum detected concentrations exceeding refined ESVs, are discussed further in the COPEC selection uncertainty section (**Section 4.6**). Constituents with 95 percent UCL_{mean} concentrations exceeding the mean background concentration were subjected to a secondary background evaluation consisting of a two-sample hypothesis test to determine if the site and background populations are significantly different (Roux, 2018b). If the site concentrations are determined to be from a different population, and the mean (or median) is greater than that of the background data plus the significant difference (1.3 times the standard deviation), then the constituent was considered to be a COPEC. Otherwise, the constituent was considered to be background-related. When two reference areas were available for either soil or sediment in a given exposure area (e.g., SO#2 and SO#3 were selected as appropriate reference areas for Flathead River Riparian Area; see **Table 4-16** and Roux, 2019) a two-sample hypothesis test was separately performed for each constituent using data from both sets of reference areas. If the result of either test indicated that the populations were not significantly different between the site and reference area, then the constituent was considered to be background-related. The results of the two-sample hypothesis testing are summarized in the COPEC refinement tables and presented in full in the Phase II DSR (Roux, 2019).

4.4.3 Frequency of Detection

Constituents that are detected infrequently may be artifacts in the data that may not reflect site-related activity or disposal practices. These constituents are not evaluated further in the risk evaluation. Generally, constituents that are detected only at low concentrations in less than 5 percent of the samples (if more than 20 samples were analyzed) were initially eliminated from further consideration. Constituents detected infrequently at elevated concentrations as compared with ESVs and/or BTVs may indicate the presence of “hot spots” and may be retained in the evaluation. The maximum detected concentrations of constituents that were detected in less than 5 percent of samples were compared to a value equal to 10-times the ESV or BTV for that constituent, whichever is greater. Although no recommendation on hot spot identification was identified in MDEQ guidance, this approach is consistent with environmental guidance on identification of hot spots in other states. For example, the Land Quality Division in the state of Oregon (State of Oregon Department of Environmental Quality, 1998) defines a soil hot spot as an area where a constituent is present at 10 times the acceptable risk level (or

up to 50 times the risk level for non-threatened or endangered species). The New Jersey Site Remediation Program (New Jersey Department of Environmental Protection, 2018) lists one of its criteria for hot spots as areas where "the magnitude of the exceedance is substantial (e.g., more than 10 times the ecological screening criteria or background concentrations)". If the maximum detected concentration exceeded this value, exceedances were plotted on a map. Professional judgment was used to evaluate whether the exceedances were spatially clustered, such that regular exposure could occur in a localized, but ecologically relevant portion of the site. Infrequently detected constituents that meet these criteria were retained as refined COPECs and evaluated for risk associated with direct contact and wildlife ingestion exposure pathways.

The frequency of detection criterion was not used in the COPEC refinement step for the Operational Area. The individual DUs that comprise the ISS sampling grid represent independent exposure areas; therefore, it is not appropriate to exclude constituents as refined COPECs that occur in a low percentage of DUs because localized disposal practices could have resulted in the site-related presence of a given constituent in a single DU. Also, small range receptors could realistically receive all (or nearly all) of their exposure within one DU; thus, the elimination of a COPEC detected in a low percentage of samples because it would be infrequently encountered by a receptor is not a valid assumption for the Operational Area, where each "sample" represents an area that is approximately 1 acre in size.

4.4.4 Nutrient Status

As described in Supplemental Component 3 of *The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments* (USEPA, 2001a), physiological electrolytes (e.g., iron, magnesium, sodium, and potassium) or macro and micro-nutrients (e.g., nitrogen, phosphorus, and copper) are considered in the broader context of their essential role in performing intracellular functions in aquatic and terrestrial flora and fauna. Within the soil, surface water, and sediment matrices evaluated as part of the ecological investigation, several constituents require further discussion pertaining to dietary considerations. Anions, cationic metals, and nutrient constituent groups are discussed below for each matrix evaluated. The anion chloride is discussed, as well as the cationic metals sodium, potassium, calcium, and magnesium. Nutrients, measured in surface water, include nitrate/nitrite-nitrogen, ammonium-nitrogen, and total orthophosphate-phosphorus. Most nutrients, cationic metals, and anions lacked ESVs in the initial COPEC screening evaluation. However, these constituents were included as they provide important ancillary information that can refine exposure criteria (e.g., BLM in surface waters) or further characterize exposure to identified COPECs. The role of these constituents as essential components of specialized intracellular functions is discussed below.

Cationic metals, including calcium, magnesium, potassium, and sodium, were evaluated in sediment and soil matrices. The range of observed constituent concentrations and means across exposure areas in site surface soil (0 to 2 ft-bgs) and sediment was compared to BTVs developed for the Site and to the range of typical values for western soils described in *Element Concentrations in Soils and other Surficial Materials of the Conterminous United States* (USGS, 1984):

Cationic Metal	CFAC Site	CFAC Site, Range of Means	CFAC Background (Range of BTVs)	Western U.S. Soils (USGS, 1984)	
	Concentration Range (mg/kg)	Concentration Range (mg/kg)	Concentration Range (mg/kg)	Geomean ± GSD Concentration (mg/kg)	Concentration Range (mg/kg)
Calcium	427 to 313,000	8,152 to 125,544	16,691 to 47,061	18,000 ± 30,500	600 to 320,000
Magnesium	442 to 27,500	6,329 to 10,607	8,275 to 16,202	7,400 ± 22,100	300 to 100,000
Potassium	101 to 10,900	678 to 1,797	1,844 to 2,167	18,000 ± 7,100	1,900 to 63,000
Sodium	26.5 to 61,300	58 to 11,037	69.94 to 293.3	9,700 ± 19,500	500 to 100,000

BTV = background threshold value
CFAC = Columbia Falls Aluminum Company, LLC
GSD = geometric standard deviation
mg/kg = milligrams per kilogram
USGS = United States Geological Survey
USGS. (1984). Element Concentrations in Soils and other Surficial Materials of the Conterminous United States. USGS Professional Paper 1270.

The range of site surficial soils and sediments exceeded the range of BTVs for all nutrients, which is not unexpected given the substantial disparity in sample size between the Site (n greater than 550) and the background (n = 10 per soil background area) datasets. With such a large sample size, the opportunity for sampling naturally occurring nutrients in a highly concentrated "nugget" in the soil matrix is high. A comparison of the mean concentrations to each exposure area reveals that with the exception of calcium, all mean ranges were below site BTVs. The range of detected concentrations for these four nutrients also fell within the geometric mean ± geometric mean standard deviation (GSD) for western conterminous U.S. soils for all cationic metals except calcium and sodium. Calcium concentrations above the upper GSD of the geometric mean for western conterminous U.S. soils were noted in soils and sediments from the South Percolation Pond Exposure Area. Only two results for sodium fell outside of the geometric mean ± GSD for western conterminous U.S. soils, and both results were well within the overall concentration range of western U.S. soils.

Calcium was not eliminated outright as a nutrient in the BERA because of its association with fluoride in fluorite (CaF_2). Fluorite is a component of feedstocks used in smelting. Thus, calcium warrants special consideration before eliminating it as a potential COPEC due its presence in a process-related material. As noted in the evaluation above, calcium was detected in site soil and sediment at elevated concentrations compared to site-specific BTVs, and only marginally within the broad concentration range of western U.S. soils. The highest mean concentration of calcium within the evaluated exposure areas occurred at the South Percolation Pond Area (mean = 125,543 mg/kg). All other exposure areas were below the maximum site-specific background BTV of 47,061 mg/kg. Thus, with the exception of the South Percolation Pond Area, the average concentration of calcium that ecological receptors are exposed to does not exceed a representative background concentration from naturally occurring areas in the vicinity of the Site. Toxicity data are generally unavailable for constituents that are essential nutrients and for that reason additional characterization of toxic effects of these constituents is challenging; therefore, calcium is not carried forward as a COPEC, but elevated levels of calcium in the South Percolation Pond Area will be discussed further in the BERA uncertainty analysis (**Section 7**).

In surface water, several essential anion, cationic metals, and nutrient constituents were measured as part of the Phase I and Phase II investigation. Calcium, chloride, magnesium, potassium, and sodium were evaluated, as well as ammonium-nitrogen, nitrate/nitrite-nitrogen, and total orthophosphate nutrients. These anions, cationic metals, and nutrients are particularly important for algal growth (Ansari and Gills, 2014). With the exception of two results for total calcium and one result for dissolved calcium in the South Percolation Pond Area, no exceedances of ESVs were noted for the anion or cationic metal compounds. Anionic and cationic metals data were collected in the Phase I and II Site Characterization for the purposes of evaluating metal constituent bioavailability (e.g., copper) using the BLM, if deemed necessary.

A summary of total (T) and dissolved (D) nutrients in surface water at the Site compared with reference areas is provided in the following table. Although maximum concentrations of all nutrients were well above BTVs, the range of mean concentrations of all nutrients approximated the range of BTVs identified in reference areas, with the exception of sodium, which had means for both total and dissolved fractions that exceeded the highest BTV in four of the six exposure areas (South Percolation Pond Area, Northern Surface Water Feature, North Percolation Pond Area, and the Flathead River) where surface water data were collected.

Cationic Metal	CFAC Site	CFAC Site, Range of Means	CFAC Background (Range of BTVs)
	Concentration Range (µg/L)	Concentration Range (µg/L)	Concentration Range (µg/L)
Calcium (T)	7,860 to 506,000	28,266 to 73,042	27,776 to 55,600
Calcium (D)	7.020 to 147,000	7,020 to 55,073	23800 to 61,264
Magnesium (T)	804 to 63,900	6,510 to 17,100	7,455 to 17,601
Magnesium (D)	384 to 24,600	384 to 15,859	5,990 to 15,852
Potassium (T)	242 to 9,100	367 to 1,426	463 to 919
Potassium (D)	237 to 9,310	389 to 1,518	354 to 751
Sodium (T)	666 to 108,000	1,410 to 19,279	1,232 to 3,064
Sodium (D)	554 to 169,000	1,730 to 18,653	809 to 2,801

µg/L = micrograms per liter
BTV = background threshold value

MDEQ developed phosphorus and nitrogen nutrient criteria for wadable streams (MDEQ, 2013) that have been reviewed and accepted by the USEPA. Cedar Creek, the only applicable water body for the criteria, did not have any exceedances for nitrogen or phosphorus compounds. The Flathead River is considered a large river under the numeric criteria framework developed by MDEQ. Large rivers require process-based mechanistic water quality models to determine appropriate criteria (MDEQ, 2013). No orthophosphate-phosphorus or nitrogen compounds were detected in the main stem of the Flathead River at levels that exceeded the criteria. Concentrations of nitrate/nitrite-nitrogen were greater than the criteria for wadeable streams in samples collected along the channel margin of the Flathead River within the Backwater Seep Sampling Area. However, elevated concentrations observed in these samples

are typical of mean groundwater nitrate concentrations in shallow groundwater within the Flathead Valley (McDonald and LaFave, 2004).

Based on analyses of the combined Phase I and Phase II Site Characterization datasets, essential nutrients were removed from further consideration in the COPEC refinement conducted as part of the BERA Problem Formulation. Elevated levels of calcium and sodium are discussed in the uncertainty analysis (**Section 7**).

4.4.5 Bioaccumulative Constituents and Food Chain Effects

Detected constituents that were not were not eliminated as COPECs because they were background-related, detected infrequently, or essential nutrients were retained for evaluation of food chain effects if they were classified as bioaccumulative. COPECs with the potential to bioaccumulate were identified for further evaluation in dietary exposure modeling based on satisfying one or more of the following criteria:

- Constituents identified as Persistent, Bioaccumulative, and Toxic Constituents as part of the USEPA Toxics Release Inventory (TRI) Program
- Constituents identified as important bioaccumulative constituents in *Bioaccumulation Testing and Interpretation for Sediment Quality Assessment* (USEPA, 2000b)
- Organic constituents with log octanol-water partitioning coefficient (log K_{ow}) values greater than 3.5 based on USEPA (2000b)
- Constituents with USEPA Eco-SSLs derived for birds or mammals

Thus, detected constituents that exceeded refined ESVs or that were determined to be bioaccumulative, and that were not removed as COPECs for one or more of the other refinement criteria were carried forward for additional evaluation. The results of the COPEC refinement are presented in the following sections.

4.4.6 Chromium

As described in **Section 4.1.1.2**, concentrations of Cr(VI) and Cr(III) were estimated using a ratio developed from site-specific Cr(VI) and total chromium data from a subset of soil samples collected during Phase II. Cr(VI) was detected in 3 of the 20 samples designated for this evaluation and was determined to comprise a less than 3 percent of total chromium in soil samples analyzed at the site. There is a high degree of uncertainty in the resulting estimations of Cr(VI) that were calculated at each exposure area using this ratio because over 85 percent of the samples analyzed for Cr(VI) used to develop the ratio were non-detect. The low proportion of Cr(VI) comprising total chromium was not unexpected, as chromium is present primarily in the Cr(III) oxidation state under typical soil conditions (USEPA, 2008c), and no known historical processes existed that would have introduced Cr(VI) into the environment at the CFAC facility. Cr(VI) toxicity data that may be used to estimate potential impacts to ecological receptors, particularly lower trophic-level organisms that comprise the base of the food chain, are limited because most sources of information used to characterize toxic effects are based on total chromium or Cr(III). USEPA Eco-SSL guidance presents toxicity reference values (TRVs) for Cr(III) and Cr(VI) for mammalian receptors, but only Cr(III) TRVs are available for birds. The mammalian TRV for Cr(III) from this guidance of 2.4 mg/kg-body weight (bw) per day (d) is lower (more conservative) than the TRV for Cr(VI) 9.24 mg/kg bw per day. The LANL ECORISK dataset presents TRVs for Cr(VI) for both birds (11 mg/kg-d) and mammals (9.24 mg/kg-d), both of which are less conservative than the TRVs used

to evaluate total chromium in the BERA (see Table 7 in **Appendix A2**). Thus, the evaluation of Cr(III) is protective of any Cr(VI) present in the environment for wildlife receptors. Therefore, as a simplified approach, although estimated (and measured, when available) Cr(VI) and Cr(III) concentrations are presented in the COPEC refinement tables for soil for each exposure area, these oxidation states of chromium are not carried forward separately as COPECs evaluated for ecological risk characterization. Only total chromium is carried forward as a refined COPEC for those exposure areas where it failed one or more of the refinement criteria, and subsequent evaluation of potential toxic effects of this metal are based on total chromium rather than speciated and estimated Cr(III) and Cr(VI) concentrations.

4.5 Refinement of COPECs

The full compilation of refined COPEC selection tables for all exposure areas and media are presented in **Appendix E**. A summary table of the results is presented in **Tables 4-17** (soil and sediment) and **4-18** (surface water). The results of the refined selection of COPECs for all exposure areas are discussed in the following subsections.

4.5.1 Terrestrial Exposure Areas

4.5.1.1 Main Plant Area

For the Main Plant Area, 13 inorganics (including metals and other inorganic parameters), dioxins, 14 individual PAH compounds and both LMW and HMW PAH categories, 2 SVOCs, and 5 VOCs were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.1.2 Central Landfills Area

For the Central Landfills Area, 14 inorganics (including metals and other inorganic parameters), dioxins, 1 PCB, 15 individual PAH compounds and both LMW and HMW PAH categories, 4 SVOCs, and 4 VOCs were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.1.3 Industrial Landfill Area

For the Industrial Landfills Area, 16 inorganics (including metals and other inorganic parameters), 9 individual PAH compounds and both LMW and HMW PAH categories were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.1.4 Eastern Undeveloped Area

For the Eastern Undeveloped Area, 13 inorganics (including metals and other inorganic parameters), 1 individual PAH compound and the HMW PAH category, and 2 SVOCs were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative

constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.1.5 North-Central Undeveloped Area

For the North-Central Undeveloped Area, 9 inorganics (including metals and other inorganic parameters), HMW PAHs, 1 SVOC, and 1 VOC were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.1.6 Western Undeveloped Area

For the Western Undeveloped Area, 9 inorganics (including metals and other inorganic parameters), dioxins, HMW PAHs, 1 SVOC, and 4 VOCs were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.1.7 Flathead River Riparian Area

For the Flathead River Riparian Area, 7 inorganics (including metals and other inorganic parameters), 1 individual PAH compound and the HMW PAH category, 3 SVOCs, and 5 VOCs were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.2 Incremental Soil Sampling Grid

As for the screening-level COPEC selection, the high-RSD adjusted dataset was used to select refined COPECs in the ISS area soil. For the Incremental Soil Sampling Grid, 18 inorganics (including metals and other inorganic parameters), 2 PCBs, 16 PAHs (and LMW and HMW PAHs), and 5 SVOCs were identified as refined COPECs in soil. These constituents were evaluated only for potential impacts associated with direct contact (plants and invertebrates), and for comparison to benchmark values protective of small range wildlife receptors.

4.5.3 Transitional Exposure Areas

4.5.3.1 North Percolation Pond Area

4.5.3.1.1 Soil

For the North Percolation Pond Area, 17 inorganics (including metals and other inorganic parameters), 16 individual PAH compounds and both LMW and HMW PAH categories, 3 SVOCs, and 6 VOCs were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.1.2 Surface Water

For the North Percolation Pond Area, 17 inorganic constituents (including both total and dissolved fractions) and 8 PAHs were identified as refined COPECs in surface water. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.1.3 Sediment

For the North Percolation Pond Area, 15 inorganics (including metals and other inorganic parameters), 17 individual PAH compounds and Total PAHs, and 1 SVOC were identified as refined COPECs in sediment. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.2 South Percolation Pond Area

4.5.3.2.1 Soil

For the South Percolation Pond Area, 11 inorganics (including metals and other inorganic parameters), 2 individual PAH compounds and the HMW PAH category, 2 SVOCs, and 1 VOC were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.2.2 Surface Water

For the South Percolation Pond Area, 14 inorganic constituents (including both total and dissolved fractions) and 1 PAH were identified as refined COPECs in surface water. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.2.3 Sediment

For the South Percolation Pond Area, 10 inorganics (including metals and other inorganic parameters), 13 individual PAH compounds and Total PAHs, 2 SVOCs, and 2 VOCs were identified as refined COPECs in sediment. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.3 Cedar Creek Reservoir Overflow Ditch

4.5.3.3.1 Soil

For the Cedar Creek Reservoir Overflow Ditch Area, 10 inorganics (including metals and other inorganic parameters), 1 individual PAH compound and the HMW PAH category, and 3 SVOCs were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for

bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.3.2 Surface Water

For the Cedar Creek Reservoir Overflow Ditch Area, 7 inorganic constituents (including both total and dissolved fractions) were identified as refined COPECs in surface water. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.3.3 Sediment

For the Cedar Creek Reservoir Overflow Ditch Area, 7 inorganics (including metals and other inorganic parameters), 14 individual PAH compounds and Total PAHs, and 3 SVOCs were identified as refined COPECs in sediment. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.4 Northern Surface Water Feature

4.5.3.4.1 Soil

For the Northern Surface Water Feature Area, 8 inorganics (including metals and other inorganic parameters) and 1 SVOC were identified as refined COPECs in soil. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.4.2 Surface Water

For the Northern Surface Water Feature Area, 6 inorganic constituents (including both total and dissolved fractions) were identified as refined COPECs in surface water. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.3.4.3 Sediment

For the Northern Surface Water Feature Area, 8 inorganics (including metals and other inorganic parameters), 10 individual PAH compounds and Total PAHs, and 3 SVOCs were identified as refined COPECs in sediment. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.4 Aquatic Exposure Areas

4.5.4.1 Flathead River

4.5.4.1.1 Surface Water

For the Flathead River, 11 inorganic constituents (including both total and dissolved fractions) were identified as refined COPECs in surface water. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in Baseline Ecological Risk Analysis (**Section 5**).

4.5.4.1.2 Sediment

For the Flathead River, 4 inorganics (including metals and other inorganic parameters), 13 individual PAH compounds and Total PAHs, 2 SVOCs, and 3 VOCs were identified as refined COPECs in sediment. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.4.2 Cedar Creek

4.5.4.2.1 Surface Water

For Cedar Creek, 4 inorganic constituents (including both total and dissolved fractions) were identified as refined COPECs in surface water. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.4.2.2 Sediment

For Cedar Creek, 3 inorganics (including metals and other inorganic parameters), 12 individual PAH compounds and Total PAHs, and 2 SVOCs were identified as refined COPECs in sediment. These constituents were carried forward to the direct contact and (for bioaccumulative constituents) food ingestion risk characterization evaluation described in the Baseline Ecological Risk Analysis (**Section 5**).

4.5.5 Hot Spot Evaluation for Infrequently Detected Constituents

As described in **Section 4.4.3**, an additional evaluation was performed for constituents that were eliminated as refined COPECs because they were infrequently detected (less than 5 percent of samples) to ensure that localized areas with elevated constituent concentrations (i.e., “hot spots”) were not inappropriately dismissed at the COPEC refinement stage. Constituents eliminated due to low frequency of detection are presented in **Table 4-19** for exposure areas and media.

The maximum detected concentrations of constituents excluded due to the frequency of detection criterion were compared to a concentration equal to 10-times the greater of the BTV and ESV. Constituents with concentrations greater than this value were candidates for additional evaluation (i.e., plotting on a map to determine if localized clusters of samples with elevated concentrations are present). The only constituents that failed this initial hot spot criterion were PCBs in Main Plant Area

soil and dissolved copper in Flathead River surface water (**Table 4-19**). Total PCBs in the Main Plant Area are comprised entirely of Aroclor 1254, which was eliminated from further evaluation in the hot spot evaluation because its maximum concentration of 0.11 mg/kg did not exceed 10-times the ESV of 0.041 mg/kg. Total PCBs were not similarly eliminated because the conservative ESV for total PCBs of 0.000332 mg/kg was carried over from the screening-COPEC evaluation to the COPEC refinement step due to a lack of alternate ESVs protective of Aroclor mixtures (**Table 4-19**). Therefore, no additional hotspot evaluation is necessary for PCBs. Dissolved copper was detected in only 2 out of 49 surface water samples in the Flathead River, and only the highest detected concentration (26 µg/L) exceeded a value equal to 10-times the BTV of 1.9 µg/L. Because only one sample with concentrations exceeding the initial hot spot criterion is present, this elevated concentration of dissolved copper is considered to be isolated, and no further evaluation or visualization of areas with high concentrations is necessary to determine if a hot spot is present in the Flathead River.

Several infrequently detected constituents across multiple exposure areas and media lack both a BTV and ESV (**Table 4-19**). Because there was no basis for their retention, these constituents were not subjected to further evaluation for hot spots. The lack of BTVs and ESVs results in a minor uncertainty for these constituents. However, all of these constituents except for 3- and 4-methylphenol were detected in a single sample. Therefore, a hot spot consisting of multiple samples with elevated concentrations could not be present for these constituents. One constituent lacking both a BTV and ESV, 3- and 4-methylphenol, was detected in Main Plant Area soil in 4 out of 120 samples with a maximum detected concentration of 0.036 mg/kg (**Table 4-19**). As a VOC, this constituent is not bioaccumulative. The low concentrations detected are not likely to impact communities of organisms in soil (i.e., plants and invertebrates), even if the detections were in a small spatial area. Therefore, this constituent was also not retained for further evaluation.

Based on the information presented above, it is highly unlikely that the elimination of constituents as refined COPECs based on low frequency of detection has eliminated any site-related constituents that may represent a hot spot where localized adverse effects to ecological receptors may occur. Therefore, none of the constituents listed in **Table 4-19** are retained as refined COPECs for additional evaluation in the BERA.

4.5.6 Refined COPEC Summary

The following sections present a summary of the refined COPECs identified by exposure medium.

4.5.6.1 Soil and Sediment

Refined COPECs identified in soil and sediment are summarized below by analytical group:

- Metals – Exceedances of refined ESVs were noted in multiple exposure areas and were most prevalent in the industrial areas (Main Plant Area, Central Landfills Area, Industrial Landfill Area, and the Incremental Soil Sample Grid).
- Cyanide – Exceedances were noted in all ecological exposure areas evaluated.
- Fluoride – Exceedances were noted in the industrial areas (Main Plant Area, Central Landfills Area, Industrial Landfill Area, and the Incremental Soil Sample Grid) as well as the North Percolation Pond Area.

- Dioxin and furan compounds – TEC concentrations exceeded soil concentrations protective of avian or mammalian exposure to 2,3,7,8-TCDD within the rectifier yards in the Main Plant Area, the Central Landfills Area, and the Western Undeveloped Area.
- PCBs – Exceedances were noted for Aroclor 1254 in the Central Landfills Area and in the Incremental Soil Sampling Grid.
- PAHs – Exceedances were primarily limited to the industrial areas (Main Plant Area, Central Landfills Area, Industrial Landfill Area, and the Incremental Soil Sample Grid), and North Percolation Pond Area. Other exposure areas where sediment was collected also had high numbers of PAHs carried forward for additional evaluation.
- Other SVOCs – Exceedances were noted in multiple exposure areas for several SVOCs, most commonly BEHP, benzaldehyde, carbazole, and di-n-butyl phthalate.
- VOCs were carried forward in many exposure areas. Cyclohexane, methyl acetate, methylcyclohexane, and xylenes were the most common VOCs carried forward for further evaluation.

4.5.6.2 Surface Water

Refined COPECs identified in surface water are summarized below by analytical group:

- Metals (dissolved) – Exceedances were noted for select metals, including aluminum for three of the four transitional exposure areas (North Percolation Pond, South Percolation Pond, and Flathead River Riparian Areas), barium (all aquatic and transitional exposure areas), cadmium (North Percolation Pond Area), and copper (North and South Percolation Ponds).
- Metals (total) – Aluminum, barium, beryllium, cadmium, copper, iron, lead, manganese, nickel, vanadium, and zinc all had concentrations in unfiltered surface water samples that exceeded criteria for the refined COPEC analysis. Barium (all transitional and aquatic exposure areas) followed by vanadium and aluminum (all transitional and aquatic exposure areas except Cedar Creek) had the most frequent exceedances.
- Cyanide – Exceedances for cyanide were observed in all transitional and aquatic exposure areas except the Northern Surface Water Feature.
- Fluoride – Exceedances were noted in only the North Percolation Pond Area.
- PAHs – PAH exceedances were either not observed or only sporadically observed in all transitional and aquatic exposure areas except the North Percolation Pond Area, which exceeded refined criteria for eight PAH constituents.
- SVOCs – The Flathead River Riparian Area had four SVOCs that exceeded criteria. The only other transitional or aquatic exposure area where SVOCs were selected as refined COPECs in surface water was the Flathead River (BEHP, which is a common laboratory contaminant and unlikely related to previous site activities).

4.6 COPEC Selection Uncertainty Analysis

Constituents were identified as COPECs in the initial screening-level COPEC selection process in multiple exposure media due to uncertainties in the screening-level exposure analysis. Constituents with uncertainties that result in some ambiguity as to whether they should be retained as COPECs are re-evaluated to assess whether the uncertainty associated with exposure to these constituents is likely to influence the overall findings and conclusions of the BERA. Constituents identified as COPECs in the BERA based on the following tiers of uncertainty were re-evaluated as part of the BERA problem formulation:

- Constituents below the detection limit with one-half of the MDL exceeding an ESV
- Detected constituents lacking ESVs

4.6.1 Constituents with MDLs Exceeding ESVs

To evaluate the potential importance of non-detected constituents with MDLs exceeding ESVs in the BERA, maximum MDLs were compared to the range of ESVs considered during COPEC selection in the COPEC screening evaluation. ESVs identified in the initial COPEC screening step were based on chronic, no effect endpoints used as ecological screening criteria by various agencies. While the minimum ESV from these sources was used in the initial conservative screening process, the range of ESVs based on chronic, no effect endpoints are considered to represent concentrations that are not likely to cause adverse ecological effects. Therefore, exposure to non-detected constituents, if present, with MDLs within the range of ESVs identified in the initial screening step is not likely to result in adverse ecological effects. Based on this rationale, non-detected constituents with MDLs below the maximum ESV identified in the screening-level evaluation are not likely to influence the overall findings and conclusions in the BERA.

An evaluation of MDLs was conducted to compare the MDLs achieved by the laboratory relative to the range of ESVs. The MDL evaluation is presented in **Tables 4-20**, **4-21**, and **4-22** for soil, sediment, and surface water, respectively. Each table presents minimum and maximum MDLs for constituents not detected in any site sample compared to minimum and maximum screening-level ESVs for each constituent.

Constituents in soil with MDLs exceeding the screening ESV also had at least one occurrence where the maximum MDL exceeded the maximum ESV (**Table 4-20**). Therefore, there is some concern that concentrations could be present in the soil at levels that are undetectable, but where adverse ecological impacts are possible. These constituents include 2 pesticides and 25 SVOCs. Pesticides have been previously determined to be of low concern at the Site. The SVOCs listed in **Table 4-20** are not known to be process related, and the fact that they were not present at detectable concentrations in over 700 soil samples reduces the level of concern regarding their possible presence. Furthermore, none are bioaccumulative constituents of concern that may significantly biomagnify in the food chain at very low concentrations. Therefore, these constituents are considered to be of low concern and are not considered further.

Similar to soil, several pesticides and SVOCs analyses in sediment samples resulted in MDLs that exceeded their sediment ESVs. Pesticides often have very low ESVs owing to their potential to biomagnify in the food chain. The ESVs are often back calculated from ingestion models with conservative assumptions and result in values that are below commonly achievable detection limits. As previously stated, however, pesticides are not considered to be site-related constituents of concern at the Site. Nineteen SVOCs and two VOCs also had MDLs that exceeded their ESVs. None of these constituents were detected in a single sediment (or soil, which was treated as sediment during wet exposure conditions in transitional exposure areas) sample. None of these constituents are known to be related to previous waste streams at the Site. SVOCs and VOCs are not typically considered bioaccumulative constituents that can biomagnify in food chains and result in toxicity for higher trophic order receptors even at very low concentrations in the target medium. Therefore, these constituents are considered to be of low concern and are not considered further.

For surface water, silver, eight pesticides, seven PCBs, one SVOC, and two VOCs had maximum MDLs that exceeded maximum ESVs (**Table 4-22**). There is minor uncertainty related to silver MDLs exceeding the range of silver ESVs for surface water. The range of detection limits for total and dissolved silver (1.3 to 1.5 µg/L) is within the range of available surface water ESVs (0.067 to 3.2 µg/L) that was used for the laboratory method sensitivity analysis presented in the Phase II Site Characterization Sampling and Analysis Plan (Roux, 2018a). The DEQ-7 acute water quality standard for silver is hardness-dependent; there is no promulgated DEQ-7 chronic water quality standard for silver (MDEQ, 2017). Based on hardness values measured in surface water samples at the Site ranging from 50 mg/L as $CaCO_3$ to 1,740 mg/L as $CaCO_3$, sample-specific DEQ-7 acute water quality standards for silver range from 1.23 to 552 µg/L. The maximum silver detection limit of 1.5 µg/L would be equivalent to the sample-specific acute water quality standard at a surface water hardness of 56 mg/L as $CaCO_3$. 278 of 279 surface water samples analyzed at the Site exceeded a hardness value of 56 mg/L as $CaCO_3$, indicating that the maximum detection limit is sufficient to detect silver concentrations at the promulgated MDEQ water quality standard in 278 of 279 surface water samples. Silver was also not known to be associated with a release at the CFAC facility and was not selected as a refined COPEC in any ecological exposure medium. Silver was not detected in surface water samples at the site and was infrequently detected in other exposure media evaluated in the BERA, indicating lack of association of silver with site-related migration pathways. Silver was detected in 1.2 percent of discrete soils samples (7 of 552) collected within the 0 to 2-feet soil interval and 1.2 percent of sediment samples (1 of 84) collected in the Phase I and II Site Characterization sampling events. (MDLs for soil and sediment did not exceed minimum ESVs for silver.) Therefore, the fact that surface water MDLs for silver are slightly above the conservative screening value presented in **Table 4-22** is acknowledged as a minor uncertainty, but the level of concern is not considered sufficient to retain silver as a COPEC in surface water.

The SVOCs and VOCs listed in **Table 4-22** are not known to be process related, and the fact that they were not present at detectable concentrations in 17 to 23 surface water samples reduces the level of concern regarding their possible presence. Furthermore, none are bioaccumulative constituents of concern that may significantly biomagnify in the food chain at very low concentrations. Therefore, these constituents are considered to be of low concern and are not considered further. Pesticides have been previously determined to be of low concern at the Site, but PCBs have been detected in portions of the Site that were formerly used for industrial processes. However, both PCBs and pesticides are strongly hydrophobic, and are unlikely to partition to surface water in appreciable amounts compared to the concentrations in sediment. Furthermore, any potential risk associated with them would be more effectively handled by addressing sediment, which would represent the source for any trace amounts of these constituents in surface water. Therefore, these constituents are considered to be of low concern and are not considered further.

4.6.2 Constituents Lacking ESVs

Constituents evaluated for COPEC refinement that lacked ESVs are presented in **Tables 4-23, 4-24,** and **4-25** for soil, sediment, and surface water, respectively. The range of BTVs across all applicable reference areas is also provided in these tables for additional information. Three SVOCs and 6 VOCs in soil lacked ESVs and could not be retained or eliminated based on comparisons to benchmark values associated with acceptable levels of ecological risk (**Table 4-23**). The three SVOCs were all detected at less than 15 percent detection frequency, with concentrations at or below 1 mg/kg. Maximum detected concentrations slightly exceeded the BTV for the two constituents for which BTVs were available. The VOCs were detected more frequently in soil (22 to 57 percent detection frequency); however, detected concentrations were all below 1 mg/kg. VOCs tend to be short-lived in soil, volatilizing to the air or

naturally breaking down due to the actions of bacteria and microbes in the soil. Further, neither the SVOCs nor VOCs on this list are expected to be bioaccumulative constituents that could pose potential risks via food chain effects. Furthermore, if retained as COPECs, few if any toxicity data are available that would allow an estimation of potential effects on ecological receptors. For these reasons, the presence of these 9 constituents in Site soil is considered a minor uncertainty that is highly unlikely to affect conclusions based on constituents for which ESVs are available.

For sediment, four metals, three SVOCs, and three VOCs were detected but lacked ESVs (**Table 4-24**). Although the four metals (barium, beryllium, thallium, and vanadium) lack ESVs based on sediment exposure, ESVs are available for them based on soil exposure. Thus, they were evaluated in the terrestrial scenario for transitional exposure areas. NOEC and LOEC data are available for potential impacts to benthic invertebrates for barium. However, little additional data are available for the other three metals to evaluate their potential toxicity in aquatic sediment. Mean and maximum detected concentrations for the four metals exceeded the maximum BTV in reference areas used to establish soil background concentrations. For the three SVOCs and three VOCs that lacked ESVs, all were detected at relatively low concentrations, with the exception of carbazole, which was detected at a maximum concentration of 190 mg/kg. Carbazole is an aromatic heterocyclic compound that is strongly associated with the presence of PAHs, and it is likely that any further activities to evaluate PAHs will also address carbazole. Although the three SVOCs had maximum concentrations that exceeded BTVs (BTVs were not available for the three VOCs), the remaining organic constituents are not known or suspected to be site-related and are not expected to pose a threat to ecological receptors through food chain effects (bioaccumulation). Therefore, the presence of these constituent in site sediment is considered a minor uncertainty that is highly unlikely to affect conclusions based on constituents for which ESVs are available.

Vanadium (unfiltered) and four SVOCs were detected but lack ESVs in surface water (**Table 4-25**). Vanadium was present at concentrations greater than its BTV. Although an ESV protective of total (unfiltered) concentrations of vanadium in surface water was not identified in the sources used for obtaining benchmarks used in the refined COPEC analysis, NOEC and LOEC values for total vanadium of 19 and 190 µg/L, respectively, were identified in LANL ECORISK (2017), and were used to evaluate total vanadium effects for direct toxicity (see **Table 5-5**). Therefore, a robust evaluation of this metal was performed in the BERA in spite of the lack of an ESV for the dissolved fraction. The four SVOCs that lacked ESVs were only detected in one or two surface water samples. BTVs were available for three of the SVOCs, and two (benzaldehyde and carbazole) were detected at maximum concentrations that exceeded their BTVs. All detected concentrations were below 10 µg/L, and none are known to be site-related or are suspected to be a threat to wildlife receptors via their bioaccumulation potential. Therefore, the presence of these constituents in site surface water is considered a minor uncertainty that is highly unlikely to affect conclusions based on constituents for which ESVs are available.

5 Baseline Ecological Risk Analysis

The following sections present the framework for the baseline risk analysis developed based on data and observational information generated as part of the Phase I and Phase II Site Characterization and integrated in the BERA Problem Formulation (**Section 3**). The Problem Formulation provides the basis for the selection of assessment endpoints, risk questions, and measurement endpoints for assessment in the BERA. Exposure estimates are developed for the identified assessment and measurement endpoints based on quantitative comparisons of EPCs derived as part of the exposure analysis to effects endpoints established based on the ecological effects analysis.

5.1 Assessment Endpoints, Risk Questions, and Measurement Endpoints

Assessment endpoints are identified to explicitly express the environmental value that is to be protected (USEPA, 1997). Measurement endpoints are qualitative or quantitative observations that are measured for each receptor category in each exposure area to evaluate the assessment endpoint. Risk questions were formulated to identify specific measurable ecological characteristics that could be used to evaluate the selected assessment endpoints. These measurement endpoints represent numerical observations that will be measured in ecological exposure areas and compared to similar observations measured at reference sites or reported in the literature (e.g., effects thresholds). The selected measurement endpoints are used in a weight-of-evidence assessment of risk to each representative receptor based on the identified assessment endpoints.

Based on the problem formulation and ECSMs presented in **Section 3**, assessment endpoints, risk questions, and measurement endpoints were formulated for terrestrial, transitional, and aquatic exposure areas identified in **Section 3.3.1** (**Figures 3-2** through **3-4**, respectively). A summary of the risk questions and measurement endpoints selected for each assessment endpoint is provided in **Table 5-1** for terrestrial exposure areas, **Table 5-2** for transitional exposure areas, and **Table 5-3** for aquatic exposure areas.

Assessment endpoints include potential exposure to special status species (Threatened or proposed Threatened) that were identified by the USFWS IPaC query (**Section 3.3.5**). Consistent with ERAGS, potential exposure to Threatened species is evaluated based on the individual level of organization, as opposed to population level (**Table 5-1** to **Table 5-3**). Measurement endpoints for Threatened species is based on comparisons of estimated daily doses to NOAEL TRVs. Further evaluation of the assessment endpoints for special status species is conducted as part of the BERA Problem Formulation. Additional considerations for these assessment endpoints include an assessment of the potential for special status species to occur in site exposure areas based on documented occurrences and the potential for suitable habitat to support the special status species. The following section presents the risk analysis approach used to support the evaluation of measurement endpoints in the BERA.

5.2 Effects Analysis

As part of the risk analysis phase, the ecotoxicity review presented in the BERA Problem Formulation (**Section 3.3.7**) was used as the basis to identify receptor-specific benchmarks to estimate the potential ecotoxicological effects of primary COPECs relevant receptor groups within terrestrial, transitional, and aquatic exposure areas at the Site. The following sections describe the basis of developing receptor-specific effects endpoints for the baseline risk analysis phase.

5.2.1 Direct Contact Exposure Pathways

The effects analysis for direct contact pathways was conducted based on literature and guidance reviews to refine direct contact ESVs to represent receptor-specific exposure. Two general tiers of endpoints were identified, as available, to evaluate the potential for adverse effects related to direct contact exposure pathways:

- NOEC: Representative of the central tendency (e.g., geometric mean) of NOEC endpoints identified for relevant test organisms in literature/database studies.
- LOEC: Representative of the low end of the distribution of LOEC endpoints (e.g., 15th percentile or bounded study endpoints) identified for relevant test organisms in literature/database studies.

When available, existing estimates of NOECs and LOECs derived in the literature or guidance based on the geometric mean of no effect endpoints was used in the BERA. If insufficient data were available to establish geometric means, established NOECs and LOECs from literature or guidance were used instead. NOEC and LOEC endpoints for direct contact pathways are presented in **Tables 5-1** through **5-3**. The following sections describe the general approach for conducting effects analyses for direct contact exposure pathways from relevant exposure media.

5.2.1.1 Soil

Potential effects associated with direct contact pathways from soils were evaluated based on literature and database reviews of NOEC and LOEC endpoints from toxicological studies. Effects endpoints were established for the receptor categories identified for direct contact pathways to soil in the terrestrial and transitional ECSMs and measurement endpoints for soil (**Table 5-4**):

- Terrestrial plant community
- Soil invertebrate community

Sources of toxicological data that were used to support the development of direct contact NOEC and LOEC endpoints for soil COPECs include:

- USEPA Eco-SSLs
- Oak Ridge National Laboratory (ORNL) Risk Assessment Information System (RAIS)
- LANL ECORISK Database
- USEPA ECOTOX Database
- Targeted literature reviews for specific COPECs and receptor categories

5.2.1.2 Surface Water

Potential effects associated with direct contact pathways from surface water were evaluated based on literature/database reviews of survival, growth, and reproduction endpoints from aqueous toxicity studies. When available, USEPA and MDEQ promulgated chronic and acute surface water quality criteria were used as the basis for NOEC and LOEC endpoints, respectively for the protection of aquatic receptors that may be exposed to surface water in aquatic and transitional exposure areas at the Site. Effects endpoints were established for the receptor categories identified for direct contact pathways to surface water in aquatic and transitional ECSMs and measurement endpoints for surface water (**Table 5-5**):

- Aquatic plant community

- Benthic and pelagic invertebrate community
- Fish and herptiles (amphibians and reptiles)

Receptor-specific surface water NOEC and LOEC endpoints were derived from a review of aqueous toxicity studies and databases for relevant test organisms to support the evaluation of measurement endpoints (**Table 5-5**). Sources of aqueous toxicity studies to support the derivation of receptor-specific surface water benchmarks include:

- USEPA NRWQC (USEPA, 2019)
- MDEQ Circular DEQ-7 (MDEQ, 2017)
- USEPA ECOTOX Database
- LANL ECORISK Database
- ORNL RAIS
- Targeted literature reviews for specific COPECs and receptor categories

Where applicable, effects endpoints that consider site-specific conditions that influence COPEC bioavailability and toxicity in surface water were preferentially selected. When available, USEPA or MDEQ promulgated chronic and acute surface water quality criteria were used as the basis for NOEC and LOEC endpoints, respectively. For metals, NOECs and LOECs were based on the phase used as the basis for surface water quality criteria. USEPA NRWQC for several metals are based on exposure to the dissolved phase, with criteria for some metals (cadmium, chromium, lead, nickel, zinc) calculated as a function of surface water hardness (as mg/L $CaCO_3$). For these metals, NOECs and LOECs were based on sample-specific hardness measurements to spatially and temporally align hardness and filtered (dissolved) metals results. For copper, NOEC and LOEC concentrations were based on the BLM, consistent with the USEPA NRWQC. In addition, recently promulgated USEPA aquatic life ambient water quality criteria for aluminum that considers the influence of hardness and pH on aluminum toxicity were used to establish NOECs and LOECs for total (unfiltered) aluminum (USEPA, 2018). MDEQ water quality criteria (chronic and acute) are based on the total (unfiltered) phase for all metals, except for aluminum. In addition to differences in surface water quality criteria for metals, USEPA evaluates aqueous cyanide exposure based on analyses of free cyanide and MDEQ evaluates cyanide exposure on the basis of total cyanide. Given the differences in the basis of surface water quality criteria for metals and cyanide between USEPA and MDEQ, effects endpoints were established and evaluated based on dissolved and total phase results for metals and free and total cyanide results.

Sources of aqueous toxicity data included sources identified for surface water, but also included final chronic values (FCVs) presented in the ESB guidance for PAH exposure in pore water (USEPA, 2003a). FCVs are considered to be protective of aquatic species in the derivation of ESBs; therefore, the FCVs are considered appropriate for direct comparisons to aquatic receptors that may be exposed to surface water.

Surface water exposure pathways for COPECs and receptor categories lacking available aqueous toxicity endpoints are addressed as an uncertainty in the BERA (**Section 7**).

5.2.1.3 Sediment

Direct contact effects associated with exposure to sediment were evaluated based on benthic invertebrate effects endpoints. When available, potential effects associated with direct contact pathways from sediment to benthic invertebrates were evaluated based on predictive models derived

using EqP relationships. The approach for deriving ESBs was based on USEPA ESB guidance for multiple constituent groups relevant to sediment exposure in aquatic and transitional exposure areas at the Site:

- PAHs: *USEPA Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures* (USEPA, 2003a)
- Divalent metals: *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: Metals Mixtures (Cadmium, Copper, Lead, Nickel, Silver, and Zinc)* (USEPA, 2005a)
- Nonionic Organic Compounds: *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: Compendium of Tier 2 Values for Nonionic Organics* (USEPA, 2008a)

For organic COPECs lacking ESB values from the above sources, site-specific ESBs were derived using the sample-specific fraction of organic carbon (f_{oc}), constituent-specific organic carbon-water partitioning coefficient (K_{oc}), and WQB based on the EqP presented in **Section 4.4.1**.

In the absence of appropriate EqP relationships to derive site-specific ESBs for COPECs, literature and database reviews were conducted to identify NOEC and LOEC endpoints from toxicological studies. Sources of toxicological data that were used to support the development of direct contact NOEC and LOEC endpoints for sediment COPECs include (**Table 5-6**):

- National Oceanic and Atmospheric Agency (NOAA) Sediment Toxicity (SEDTOX) Database
- ORNL RAIS
- LANL ECORISK Database
- Targeted literature reviews for specific COPECs

5.2.1.4 Pore Water

Potential effects associated with direct contact pathways to pore water were evaluated based on literature and database reviews of survival, growth, and reproduction endpoints from aqueous toxicity studies. When available, pore water NOEC and LOEC benchmarks were derived for each receptor category that may be exposed to pore water in the ECSM (aquatic plants, benthic invertebrates, amphibians) using aqueous toxicity endpoints for test organisms representing each receptor category. Sources of aqueous toxicity data included sources identified for surface water, but also included FCVs presented in the ESB guidance for sediment (USEPA, 2003a). FCVs are considered to be protective of aquatic species in the derivation of ESBs; therefore, the FCVs are considered appropriate for direct comparisons to pore water to evaluate potential effects to benthic invertebrates. WQBs derived for the protection of general aquatic life are considered protective of all receptor categories that may be exposed to pore water.

Consistent with the derivation of surface water effect endpoints, the derivation of pore water effects endpoints considered site-specific conditions that influence COPEC bioavailability and toxicity. Site-specific conditions in pore water that were considered in the development of effects endpoints included:

- Pore water pH: Influences the bioavailability and toxicity of cyanide, aluminum, and other metals.
- Pore water hardness: Criteria for the dissolved phase of select metals is a function of pore water hardness (as $CaCO_3$).

- Free cyanide: Represents the bioavailable and potentially toxic form of cyanide. Toxicity studies based on free and total cyanide were included for evaluation, consistent with USEPA NRWQC (which are based on free cyanide) and DEQ-7 values (which are based on total cyanide).

In the absence of available aqueous toxicity endpoints for specific receptor categories, chronic surface water quality criteria for the protection of aquatic life promulgated by the USEPA NRWQC or MDEQ were considered default NOECs for the protection of receptors that may be exposed to pore water.

5.2.2 Ingestion Exposure Pathways

For ingestion pathways, the effects analysis included a detailed review of TRVs derived from toxicological studies to evaluate the potential for adverse ecological effects associated with the dietary doses estimated using the approaches described in **Section 5.3.3**. Two tiers of chronic TRVs representing NOAELs and LOAELs for growth, reproduction, and survival endpoints were identified to evaluate the potential for adverse effects via ingestion pathways:

- Low, NOAEL-based TRV (TRV_{NOAEL}): Represents the geometric mean NOAEL TRV identified in literature studies.
- High, LOAEL-based TRV (TRV_{LOAEL}): Represents a TRV based on chronic exposure, that estimates a geometric mean LOAEL in literature studies.

The two tiers of TRVs were used to evaluate potential wildlife exposure based on estimated daily doses (EDDs) calculated using screening-level. TRVs were obtained primarily from peer-reviewed compilations of toxicity data for ecological risk assessment from sources including, but not limited to:

- USEPA Eco-SSLs
- ORNL *Toxicological Benchmarks for Wildlife*: 1996 Revision (Sample et al., 1996)
- LANL ECORISK Database
- Targeted literature reviews for specific COPECs and receptor categories

In addition, at the request of USEPA, LOAELs provided in TechLaw (2008) and the approach for deriving TRVs presented in that document were also considered in the selection of TRVs. TRVs presented in *Development of Toxicity Reference Values for Conducting Ecological Risk Assessment at Naval Facilities in California, Interim Final* (Engineering Field Activity West, 1998) were also considered as a source for toxicity reference values. The TRVs selected for use in the BERA, and the basis for deriving TRVs from literature and database searches was presented in an interim deliverable to the BERA Work Plan, which is included in **Appendix A2**.

5.3 Exposure Analysis

Risk estimates were developed in the BERA using data and observational information generated as part of the Phase I and Phase II Site Characterization. Risk estimates were based on quantitative comparisons of EPCs to effects thresholds established based on the refined ecological effects analysis discussed in the preceding section. EPCs for mobile receptors were based initially on maximum concentrations, and refined assumptions were used to develop conservative estimates of average concentrations that receptors could be exposed to during their foraging activities. EPCs for risk estimation via direct contact and ingestion pathways were calculated based on UCL_{mean} COPEC concentrations to represent a conservative estimate of average exposure conditions over an exposure area.

5.3.1 Calculation of Exposure Point Concentrations

EPCs to evaluate exposure in the BERA were estimated for each exposure area using data collected as part of the Phase I and Phase II Site Characterizations. EPCs were calculated to represent a range of exposure scenarios:

- Maximum EPC: Represent a reasonable maximum exposure scenario based on the maximum measured concentration in each exposure area.
- Refined EPC: Represent likely exposure scenarios based on random exposure throughout each exposure area.

Refined EPCs for risk estimation via direct contact and ingestion pathways were calculated based on UCL_{mean} COPEC concentrations to represent average exposure conditions over an exposure area. UCL_{mean} concentrations were calculated using USEPA ProUCL software (version 5.1 or later) and the statistical approach described in the USEPA ProUCL Version 5.1 Technical Guidance (USEPA, 2015b). Although 95 percent UCLs were the target values to use as the refined EPCs, the term "UCL_{mean}" is used in this report because, at times, UCL values other than the 95 percent UCLs were selected as EPCs based on ProUCL outputs. In general, the 95 percent UCLs recommended in ProUCL were used as the refined EPC in the risk estimate. When the UCL recommended by the ProUCL software exceeded the maximum detected concentration, the most conservative UCL derived using the Chebyshev method that produced a result lower than the maximum was selected as the UCL_{mean} and adopted as the refined EPC. ProUCL input and output data are presented in **Appendix I**. All UCLs selected as EPCs had a confidence limit of 95 percent or greater, except for three UCL_{mean} values that had confidence limits of 90 percent. A summary of the types of UCLs selected as the refined EPCs by media is presented in the following table:

Type of Upper Confidence Limit (UCL) of the Mean	Soil/Sediment UCLs	Soil UCLs	Surface Water UCLs
90% UCLs	2	1	0
95% UCLs	483	265	77
97.5% UCLs	13	0	2
99% UCLs	4	0	2
Other (e.g., Gamma-adjusted Kaplan-Meier UCL)	28	9	8

In addition to UCL_{mean} EPCs, exposure was also evaluated on a point-by-point basis for sedentary receptors, such as plants, soil invertebrates, and benthic invertebrates, and wildlife receptors with small home ranges (e.g., meadow vole, short-tailed shrew). The evaluation of potential exposure on a point-by-point basis supports a spatial evaluation where sedentary or small home range receptors may be exposed to localized concentrations in soil that may result in adverse effects. Further discussion of the approach for evaluation exposure to small home range wildlife receptors is presented in **Section 5.3.3.2.2**.

EPCs were developed in the Operational Area for individual ISS DUs for the purpose of evaluating potential risk to sessile or small range receptors that would receive 100 percent of their exposure within a given DU; ISS data collected within the Operational Area were not evaluated for exposure to large-range receptors. The Operational Area where the ISS sample grids are located represents a sub-area that overlaps two ecological exposure areas, specifically the Central Landfill Area and the Main Plant

Area. ISS samples were only collected in a sub-area of the facility where the locations of specific source areas and migration pathways were not known. ISS results (i.e., the concentrations resulting from the single replicate adjusted for the variance within the DUs with triplicate samples or the UCL_{mean} calculation performed on these DUs with replicates) were evaluated for each grid based on point-by-point comparisons with ecological benchmarks to evaluate soil exposure to plants, soil invertebrates, and wildlife receptors with foraging ranges less than the size (approximately 1 acre) of the ISS DUs. Because the home ranges for these receptors are approximately equal to or smaller than the size of the DUs, no adjustment for spatial use (e.g., and AUF) was used to adjust the DU EPC. ISS triplicate UCL_{mean} calculations and the DU-adjusted concentrations are presented in **Appendix J**. For the four DUs with triplicate incremental samples, UCL_{mean} values were calculated for constituents that were detected in at least one of the three incremental samples using the ITRC calculator as described in **Section 4.1.1.1**. One-half the method detection limit was used as the surrogate values for non-detects (ITRC, 2012a and 2012b). $UCLs_{mean}$ calculated using only three results will always be greater than the maximum detected concentrations; therefore, the UCL generated by the ITRC UCL calculator was always selected as the EPC for the ISS triplicate sample results. EPCs for DUs where only a single incremental sample was collected were adjusted based on the variance observed for each constituent in each soil depth interval, as reflected by the average RSD for that constituent across the four DUs where triplicate samples were collected. The equation showing this adjustment is presented in **Section 4.1.1.1**.

As part of the broader, facility-wide investigation, discrete soil samples were also collected within the ISS sampling grid footprint during Phase I and Phase II Site Characterization. Data from these discrete samples were evaluated separately from the ISS evaluation; due to different underlying statistical properties, it is not appropriate to combine data derived from ISS and discrete samples to calculate statistical parameters that reflect an overall exposure to the area (e.g., UCL_{mean} EPCs for large-range receptors). Discrete samples were collected (including within the Operational Area) to fully characterize potential risk to ecological receptors across the entire Site. Therefore, data from discrete samples that were located within the ISS grids were evaluated in a manner consistent with other discrete soil samples, i.e., they were evaluated on a point-by-point basis for comparison to benchmarks protective of small-range and sessile receptors, and they were included in the larger exposure area dataset for evaluation of the protection of larger ranging receptors. A discussion of the differences in concentrations between the discrete and ISS soil samples collected within the Operational Area is presented in the Uncertainty Analysis (**Section 7.12**).

5.3.2 Direct Contact Exposure Pathways

Direct contact exposure pathways identified in the ECSM were evaluated based on comparisons of EPCs to receptor-specific effects endpoints (**Section 5.2.1**). As stated in the preceding section, direct contact exposure evaluations included a range of exposure conditions based on maximum EPC and refined EPC scenarios. Maximum and refined EPCs were compared to NOEC and LOEC endpoints to evaluate the potential for adverse effects based on a range of effects endpoints.

5.3.3 Ingestion Pathways

The evaluation of potential exposure via direct and incidental ingestion pathways was conducted based on a tiered approach in accordance with the USEPA guidance for conducting probabilistic ecological risk assessment (USEPA, 2001b). The tiered approach utilizes deterministic and then, if necessary, probabilistic exposure modeling if additional analysis is warranted (e.g., if deterministic modeling

exceeds doses associated with LOAELs). Deterministic exposure modeling is based on conventional single point estimates of EPCs and typical exposure parameters, while probabilistic exposure modeling estimates exposure based on the distributions of EPCs and exposure parameters to account for variability and/or uncertainty in model parameters. The results of the deterministic model were reviewed, and although LOAEL-based exceedances were observed, it was determined that additional information obtained through probabilistic modeling would not materially affect conclusions or provide additional insight into recommendations or conclusions. Therefore, probabilistic modeling was not performed in this BERA.

Wildlife receptors identified in **Section 3.3.6** as being representative of the foraging guilds present at the Site were evaluated for potential food chain effects resulting from ingestion of prey items exposed to contamination in Site media. Life history characteristics affecting parameters that are critical for estimating exposure (e.g., body weight, ingestion rate) are presented in the wildlife modeling interim deliverable in **Appendix A2**. Also presented in that interim deliverable are the various uptake models used to estimate concentrations in prey or food items, TRVs that reflect NOAELs and LOAELs, complete descriptions of the ingestion and dose modeling equations, and other supporting information necessary to interpret the results of the ingestion modeling.

5.3.3.1 Model Structure

Dietary exposure estimates consider the typical dietary preference and composition for each receptor, in terms of representative dietary items at the site. Exposure estimates for ingestion pathways were based on comparisons of receptor-specific EDDs calculated from simple dose rate models to TRVs. The general form of the dose rate model used to calculate EDDs in both modeling scenarios is as follows:

$$EDD = \frac{1}{BW}\sum_{i=1}^{N}\left(FIR_{dw} \times \sum_{j=1}^{M}(f_j \times C_j) + SIR \times C_{sub} + WIR \times C_{sw}\right)_i \times AUF_i$$

where:

i = Number of exposure areas
j = Receptor-specific dietary items
BW = Receptor-specific body weight
FIR_{dw} = Receptor-specific daily food ingestion rate (dry weight)
f_j = Proportion of dietary item *j* to total dietary composition
C_j = COPEC concentration in dietary item *j*
SIR = Receptor-specific incidental sediment ingestion rate
C_{sub} = COPEC concentration in substrate (sediment or soil)
WIR = Receptor-specific daily drinking-water ingestion rate
C_{sw} = COPEC concentration in unfiltered surface water
AUF_i = Area use factor

It should be noted that dietary exposure to fish was not evaluated for transitional areas, as these areas do not sustain an aquatic environment capable of supporting fish populations to provide a sufficient forage base for piscivorous wildlife.

A modified version of the model was used to evaluate the potential additive exposure to dioxin and furan compounds in surface soil sampled within the Main Plant Area and adjacent areas. The modified dietary exposure model calculated an EDD for the 17 individual dioxin and furan compounds in each sample based on measured concentrations and soil-to-biota bioaccumulation factors (BAFs). The EDD for each compound was multiplied by the compound-specific TEF for birds or mammals to estimate the TEC for each compound (Van den Berg et al., 2006; Van den Berg et al., 1998; USEPA, 2008b). TECs of the 17 dioxin and furan compounds in each sample were summed to calculate an overall TEC for the sample. Thus, the EDD was calculated for each dioxin/furan congener as described in the above equation, multiplied by the congener-specific (bird or mammal) TEF, and then summed with the other congener EDDs to calculate the TEC. The TEC for each sample was evaluated relative to avian or mammalian dietary TRVs for 2,3,7,8-TCDD.

5.3.3.2 Modeled Scenarios

A screening-level and refined food chain model was performed for the Site. The screening-level model used maximum exposure concentrations and did not use an area use factor (AUF) to estimate risk to large-range receptors. The refined food chain model used a conservative estimate of the mean (i.e., UCL_{mean} concentrations) as the exposure concentrations, and incorporated AUFs to adjust risk for receptors that have home ranges that are larger than the exposure area being evaluated.

In addition to the screening-level and refined model scenarios, additional scenarios were evaluated for: 1) large home range wildlife receptors that may forage in multiple exposure areas throughout the site and 2) small home range receptors that may forage entirely within a small portion of an exposure area. A description of the modeled scenarios for large and small home range receptors is provide below.

5.3.3.2.1 Large Home Range Receptors – Spatially Weighted Exposure Evaluation

As described in **Appendix A2**, large home range receptors that may receive exposure from adjacent (non-target) exposure areas as well as the target exposure area were evaluated using a spatially weighted approach in the refined model. Essentially, an AUF-adjusted dose for each constituent was calculated based on the percentage of the particular receptor home range that is comprised of the target exposure area as well as all adjacent exposure areas that fell within the home range (assuming the receptor was placed in the geographic center of the target exposure area). Areas outside of the Site boundary that fell within a receptor home range were included in the spatial weighting and assigned a dose of zero. Depending on the overlapping footprints of an assumed circular home range with an irregularly shaped exposure area boundary, this approach occasionally resulted in doses from adjacent exposure areas strongly influencing the exposure estimates, particularly for receptors with small to moderately sized home ranges that may forage entirely within a single exposure area. At the request of USEPA, an AUF of 1 was applied for receptors whose home range was less than the size of the exposure area; the entire dose for that receptor was assumed to originate within the target exposure area.

Area-weighted doses from exposure areas within the potential foraging range of receptors were summed to estimate the total aggregate dose for that receptor. Constituents with HQs below 1 for any given exposure area were assumed to have negligible contribution to adjacent exposure areas for that constituent. The percentages of various exposure areas that fall within large-range receptor home ranges are presented in **Table 5-7**. The "target" exposure area being evaluated is presented vertically in the second column, and the areas to which the receptor is exposed to (given a circular home range originating within the geometric centroid of each target exposure area) are presented horizontally, with the percentage of exposure for each presented in the table. For example, the American woodcock with a home range of 11.1 acres, evaluated for the South Percolation Pond Area, receives 22.4 percent of its modeled dose from the South Percolation Pond Area, 0.4 percent from the Main Plant Area, 69.6 percent from the Flathead River Riparian Area, and 7.6 percent from unimpacted areas outside the Site boundary. This spatial weighting was only performed for terrestrial receptors that may forage randomly between terrestrial and transitional exposure areas. Although many species that forage on fish and benthic invertebrates are likely to utilize multiple water bodies during their daily activities, aquatic receptors (i.e., the American dipper, belted kingfisher, and mink) were assumed to receive 100 percent of their exposure to media within the transitional or aquatic exposure area evaluated.

5.3.3.2.2 Small Home Range Receptors – Point-by-Point Exposure Evaluation

A point-by-point evaluation of soil sample results was performed to evaluate the potential for adverse effects to small range receptors that may be exposed to COPECs in foraging ranges smaller in spatial scale than the ecological exposure areas that were used to evaluate medium- and large-range receptors. The life-history characteristics of the wildlife receptors of concern were reviewed, and the meadow vole (home range = 1 acre) and the short-tailed shrew (home range = 0.13 acre) (Table 2 in the wildlife modeling interim deliverable for the BERA Work Plan presented in **Appendix A2**) were selected as the small range receptors of concern for this evaluation.

Consistent with the approach used to calculate USEPA Eco-SSL values (USEPA, 2005b), the general exposure model presented in **Section 5.3.3.1** was used to back-calculate soil benchmark concentrations from TRVs using the *Goal Seek* function in Microsoft Excel. Back-calculated soil benchmarks for each representative small home range receptor were calculated by setting the EDD equivalent to the TRV and solving for the concentration in soil or sediment (C_{soil}). Soil benchmarks were calculated based on

TRV_{NOAEL} and TRV_{LOAEL} values (**Section 5.2.2**). TRV_{NOAEL} and TRVLOAEL -based soil benchmarks were compared on a point-by-point basis to soil data from discrete samples, as well as the individual ISS DU results from the Operational Area (see **Section 5.3.1** for a description of DU EPC calculations) from the relevant exposure intervals. Comparisons of TRVNOAEL and TRVLOAEL -based benchmarks to soil data from relevant exposure intervals are presented visually within each exposure area to illustrate potential station-specific risks to small home range receptors. Soil benchmarks protective of small range-receptors are presented in **Table 5-8**. The full description of the small range receptor evaluation—including maps indicating where exceedances occurred—is presented in **Section 6**.

5.3.3.3 Exposure Point Concentrations

EPCs for soil, sediment, or surface water inputs into screening-level exposure models were initially based on the maximum measured concentration in each exposure medium to represent the most conservative exposure scenario. A refined version of the model was run using EPCs that reflected a conservative estimate of the central tendency of exposure (e.g., UCL_{mean} concentration) to estimate the average dose that a receptor may experience while foraging randomly within an exposure area.

As described in the wildlife modeling interim deliverable to the BERA Work Plan presented in **Appendix A2**, most receptors were assumed to be exposed primarily to soil in only the shallow (0 to 0.5 foot) sampling interval. For receptors whose life history patterns indicate the potential for regular exposure to deeper soil (e.g., the short-tailed shrew, meadow vole, long-tailed weasel, and North American wolverine; note that the shrew was not included as a receptor that would likely encounter deeper soil in the BERA wildlife modeling interim deliverable presented in **Appendix A2**, however, after reviewing its foraging patterns, it is included as a burrowing receptor in the BERA), dietary ingestion pathways associated with soils were based on depth-weighted average concentrations of sampling intervals collected from 0 to 0.5 ft-bgs and 0.5 to 2.0 ft-bgs to provide a representative EPC for each soil boring station. Depth-weighted average concentrations for the 0 to 2 ft-bgs sampling interval were calculated as follows:

$$C_{sub,0-2ft} = C_{sub,0-0.5ft} \times \frac{0.5ft}{2ft} + C_{sub,0.5-2ft} \times \frac{1.5ft}{2ft}$$

where:

$C_{sub,x\text{-}y\ ft}$ = Concentration in sampling interval starting from *x* to *y* ft-bgs.

In some cases, data were only available for one interval but not both. In these cases, it was assumed that the concentration present in the sampled depth interval represented the concentration present in the entire 0 to 2 feet depth range. Most commonly, a 0 to 0.5-foot sample was collected, but not a 0.5 to 2 feet sample, rather than the reverse scenario. As described in **Section 3.6** and **Section 4.1.1**, an evaluation of the Phase I and Phase II Site Characterization data indicated that COPEC concentrations are generally greater in surface and shallow intervals and decrease with increasing soil depth (EHS Support, 2018 and 2019). Therefore, the use of data from the only interval sampled when data from both soil depth intervals were not available likely results in a conservative EPC for soil.

For surface water in the screening-level food chain models, the maximum detected concentration for each COPEC across all exposure areas was selected as the EPC for the source of drinking water for terrestrial exposure areas. Thus, it was assumed that ecological receptors would drink exclusively from

the surface water bodies at the Site with greatest exposure to surface water COPECs. This is a conservative assumption; receptors with large home ranges would ingest drinking water from multiple sources, and the origin of the water body where the maximum concentration was detected may be well outside the home range for small range receptors in terrestrial exposure areas. For transitional and aquatic exposure areas, the maximum concentrations detected from the water bodies located within each exposure area was used as the exposure concentration.

For the refined version of the wildlife ingestion models, the $UCL_{mean,}$ concentration (or the average concentration, using the quantitation limit as a surrogate for non-detected results if a constituent had too few detections to calculate a UCL) from the surface water body present at transitional and aquatic exposure areas was used as the EPC. For receptors in terrestrial exposure areas, the UCL_{mean} of the sitewide surface water dataset was calculated and used as the EPC for drinking water exposure. No adjustment was included to account for the fact that different numbers of samples were collected from the various water bodies; however, the water bodies with the larger number of samples were also larger in area and/or had the greatest probability of being used as drinking water sources. Therefore, any bias in the estimation of surface water EPCs associated with the unequal sampling design between the water bodies is considered a minor uncertainty in the BERA.

The approach to estimating drinking water EPCs deviates slightly from the BERA Work Plan and *Technical Memorandum: Proposed Wildlife Exposure Modeling Approach to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site* (EHS Support, 2018 and EHS Support, 2019b), which stated that the surface water EPCs for small-range receptors in terrestrial exposure areas would be calculated based on a subset of surface water features closest to the target exposure area. After an initial review of the data, it was determined that performing these extra calculations was not necessary and did not add any information to the BERA that would affect conclusions. For example, for most constituents and receptors, less than 1 percent of the total dose originated from drinking water ingestion. Furthermore, the maximum concentration and the UCL_{mean} for each water body were used as the EPCs for the transitional and aquatic food chain models. Thus, any potential impacts associated with drinking water from the individual water sources at the Site were clearly demonstrated in the modeling performed for the transitional or aquatic exposure area in which they were located. Calculating an EPC based on a combination of multiple water bodies based on proximity would be unnecessary, particularly when the results from the individual surface water bodies resulted in very low exposure resulting from drinking water ingestion. The use of the site-wide and exposure area-wide maximum concentrations in the screening-level wildlife ingestion evaluation and the site-wide and exposure area-wide UCL_{mean} values in the refined wildlife ingestion evaluation provide sufficient information to identify potential risks associated with drinking water under conservative and more representative exposure scenarios.

5.3.3.4 Model Parameters

Dietary exposure models include parameters relating to receptor-specific exposure factors, EPCs, and AUFs. Exposure factors refer to receptor-specific variables (e.g., BW, FIR_{fw}, SIR, WIR), which are typically derived from literature sources. Exposure variables refer to site-specific measurements, namely COPEC concentrations estimated in exposure media. The approach for estimating exposure factors and variables for wildlife ingestion pathways is summarized below. The receptor-specific exposure parameters for each surrogate receptor used in the dietary exposure modeling are presented in the wildlife exposure modeling interim deliverable that was submitted and approved prior to the initiation of the BERA. The interim deliverable is presented in **Appendix A2.**

The USEPA *Wildlife Exposure Factors Handbook* ("the Handbook" [USEPA, 1993]) was the primary data source of exposure factors for the wildlife receptor species used to represent the receptor categories identified in the ECSM (**Section 3.6**). Additional receptor-specific literature sources were also used to supplement exposure data compiled in the Handbook (e.g., USACHPPM, 2004). Deterministic exposure modeling uses exposure factors that are representative of typical or average (e.g., mean parameter) exposure conditions.

Based on the conceptual study design, dietary pathways were evaluated based on the estimates of the bioaccumulation of COPECs into dietary items from soil, sediment, and surface water pathways. Concentrations of COPECs in dietary items were estimated using conservative assumptions of BAFs, biota-sediment accumulation factors (BSAFs) from sediment, or bioconcentration factors (BCFs) from surface water. The wildlife exposure modeling interim deliverable in **Appendix A2** summarizes the bioaccumulation models used to support dietary modeling in the BERA.

5.4 Risk Calculation

Potential risks associated with exposure estimates presented in the BERA are expressed as HQs, and are calculated as the ratio of the EPC to ESV for the direct contact pathway and the summed EDD for ingestion pathways to the TRV for ingestion pathways, as follows:

$$HQ = \frac{EPC}{ESV} or \frac{EDD}{TRV}$$

Potential ecological risk may be characterized based on HQs for direct and ingestion pathways, as follows:

- $HQs_{NOEC/NOAEL}$ less than or equal to 1.0 indicates limited potential for adverse effects because constituent concentrations result in an exposure that has not been demonstrated to cause adverse ecological effects.
- $HQs_{NOEC/NOAEL}$ greater than 1.0 indicates that an EPC or EDD for the constituent exceeds an ecological benchmark representing a NOEC or NOAEL. The exposure may or may not constitute an actual risk; however, the potential for adverse effects cannot be dismissed and further evaluation is warranted.

HQs calculated based on LOEC ESVs or TRV_{LOAEL} were used to assess the likelihood of adverse effects based on exposure to concentrations or doses known to be associated with an adverse effect on survival, growth, or reproduction. The relative frequency and magnitude of LOEC ESVs or TRV_{LOAEL} exceedances were used to identify potential risk drivers within receptor groups and exposure areas.

6 Baseline Risk Estimates and Risk Characterization

Risk characterization in the BERA focuses on establishing causal relationships, if present, between ecological effects and site-specific exposure to COPECs. A description of potential ecological risks is documented in the BERA for each assessment endpoint based on the findings and interpretations of risk estimates from corresponding measurement endpoints. The risk description provides a weight-of-evidence evaluation of the likelihood and ecological significance of the estimated risks and may be used to support risk management decision-making (USEPA, 1997). Key elements included in the BERA risk description include:

- Identifying thresholds for ecological effects for observed exposure-response relationships;
- Estimating the likelihood of adverse ecological effects;
- Evaluating the spatial extent of ecological risk within exposure areas; and,
- Assessing the potential for identified risks to persist in the future, considering the potential for natural recovery once the sources of COPECs or migration pathways to the exposure area are mitigated.

This section presents risk estimates for direct contact and ingestion pathways and characterizes risk for individual exposure areas within the terrestrial, transitional, and aquatic habitat categories. Along with wildlife ingestion summaries and small range receptor exceedance maps, direct contact risk estimates are presented in **Table 6-1** through **Table 6-56** and **Figure 6-1** through **Figure 6-41**. **Appendix H** includes receptor- and exposure-area specific wildlife ingestion modeling calculations for the screening-level (**Appendix H1**) and refined (**Appendix H2**) model scenarios. Screening-level and refined modeling results are summarized in **Table 6-57** through **Table 6-59**. **Table 6-57** presents an overall summary of COPECs with an HQ_{NOAEL} that exceeded 1 in the screening-level evaluation. **Table 6-58** presents the numerical results of the refined evaluation, which calculated spatially weighted HQs based on exposure to exposure areas within a given receptor home range. Therefore, the HQs presented in **Table 6-58** represent exposure to the target and adjacent exposure areas within the home range for each receptor, using the weighting factors for exposure presented in **Table 5-7**. **Table 6-59** presents HQs using the refined EPCs (i.e., UCL_{mean} values), but the calculations assumed that the entire exposure for a given species was obtained within the target exposure area (i.e., the AUF was set to 1). These results provide a clearer visualization as to where potential risks are originating from between exposure areas. For example, using the spatially weighted approach presented in **Table 6-58**, a medium- or large-range receptor being evaluated for a relatively small exposure area (e.g., the Cedar Creek Reservoir Overflow Ditch) may exhibit high HQs for some constituents that are present primarily or even exclusively in adjacent exposure areas. By cross-checking against the results in **Table 6-59**, it can readily be observed whether the risk is originating at the target or adjacent exposure areas. The following subsections present the output of the exposure estimate and risk characterization, which provides the basis for the BERA conclusions and recommendations.

6.1 Terrestrial Exposure Areas

The following sections present risk estimates and risk characterizations for exposure areas within terrestrial habitats at the Site.

6.1.1 Main Plant Area

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial exposure in the Main Plant Area.

6.1.1.1 Direct Contact Risk Estimate

The evaluation of direct contact pathways for terrestrial plants and soil invertebrates exposed to surface soil within the Main Plant Area indicates limited potential for adverse ecological effects associated with exposure to LMW and HMW PAHs. No COPECs were detected at concentrations exceeding LOECs for terrestrial plants and soil invertebrates in the Main Plant Area. The greatest exposure to soil invertebrates was associated with exposure to LMW and HMW PAH exposure in surface soil. Maximum exposure concentrations exceeded soil invertebrate NOECs for LMW PAHs (HQ_{NOEC} = 19) and HMW PAHs (HQ_{NOEC} = 35.7), with minor exceedances for arsenic (HQ_{NOEC} = 1.3), mercury (HQ_{NOEC} = 5.4), and zinc (HQ_{NOEC} = 2.0; **Table 6-1**). Based on refined EPCs, COPECs were below NOEC values for soil invertebrates, except for exposure to LMW PAHs (HQ_{NOEC} = 2.2) and HMW PAHs (HQ_{NOEC} = 4.3).

Maximum exposure concentrations resulted in minor exceedances of terrestrial plant NOECs for nickel (HQ_{NOEC} = 3.7), selenium (HQ_{NOEC} = 1.3), and zinc (HQ_{NOEC} = 1.5); however, terrestrial plant NOECs were not available for LMW and HMW PAHs (**Table 6-1**). Refined EPCs were below available NOEC values for terrestrial plants.

Figure 6-1 illustrates the spatial distribution of sampling stations within the Main Plant Area that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. Exceedances of NOECs were primarily associated with exposure to PAHs and select metals at soil sampling stations in the north-central portion of the Main Plant Area.

6.1.1.2 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to soil in the Main Plant Area and used maximum concentrations as the EPCs resulted in HQs exceeding 1 for all receptors except for the long-tailed weasel and the North American wolverine (**Table 6-57**). Exposure to PAHs, BEHP, and dioxins resulted in the highest HQs within this exposure area (**Appendix H**).

The refined food chain model using more realistic assumptions resulted in several constituents having an HQ greater than 1, but only HMW PAHs (American woodcock and yellow-billed cuckoo) had HQ_{LOAEL} values that exceeded 1 (**Table 6-2, 6-58**). The yellow-billed cuckoo, currently listed as a federally threatened species, had HQ_{NOAEL} values that equaled 1 for LMW PAHs and exceeded 1 for HMW PAHs (19.7), BEHP (4.2), and dioxins/furans (2.7; **Tables 6-2, 6-58**). All HQ_{LOAEL} values were less than 5. Approximately 99 percent of the woodcock dose and 82 percent of the yellow-billed cuckoo dose that resulted in the LOAEL exceedances were associated with ingestion of earthworms (**Appendix H**).

Because the refined evaluation considers cumulative doses across multiple exposure areas for large range receptors, it is helpful to also evaluate potential risk associated with an exposure area assuming that 100 percent of exposure originates in that area in order to understand contributions from the target area itself rather than adjacent areas. For the Main Plant Area, the dose associated with PAHs in soil associated with risk to the American woodcock and yellow-billed cuckoo originates entirely from the

Main Plant Area, assuming exclusive foraging within this exposure area (**Table 6-59**). Furthermore, PAHs were not determined to be background-related by the background hypothesis testing evaluation performed for this exposure area (Roux, 2019).

The results of the small range receptor evaluation for the Main Plant Area are presented in **Figure 6-2**. Similar to the spatial distribution of direct contact exceedances, a cluster of stations in the north-central portion of the main industrial complex near the location of the former Paste Plant had concentrations that exceeded the NOAEL-based soil benchmark and some that exceeded the LOAEL-based soil benchmark for the short-tailed shrew. A few additional sample locations (CFSB-080 and CFSB-236) to the southeast of the main industrial complex in the vicinity of the Rectifier Yards also had concentrations that exceeded the LOAEL-based benchmark for the short-tailed shrew. Most of the samples around the periphery of the Main Plant exposure area either did not exceed either benchmark, or only exceeded the NOAEL-based benchmark (but not the LOAEL-based benchmark) for small range receptors.

6.1.1.3 Risk Characterization

Risk estimates for the Main Plant Area indicate the potential for adverse effects associated with exposure to PAHs in soil within localized portions of the Main Plant Area in close proximity to former operations. Direct contact exposure to PAHs in Main Plant Area may potentially result in adverse effects to terrestrial invertebrates in these localized areas. Maximum and refined EPCs exceeded NOECs; LOEC values were not available. Risk to plants via direct contact is expected to be negligible.

Based on refined exposure modeling that assumed that the Main Plant Area was the center of the home range of each receptor, estimated doses of PAHs resulted in wildlife ingestion HQ_{NOAEL} (for the yellow-billed cuckoo) or HQ_{LOAEL} values that exceeded 1 for the American woodcock and yellow-billed cuckoo. The ingestion of terrestrial invertebrates in the diet was the critical exposure pathway for these constituents for both receptors. Most of the samples with the highest concentrations of HMW PAHs were in the north central to eastern portion of the Main Plant Area.

BEHP also had HQ_{LOAEL} values that exceeded 1, but BEHP is a common laboratory contaminant, and its presence is unlikely to be site-related. Because of its current status as a federally threatened species, the yellow-billed cuckoo is evaluated on the basis of NOAEL endpoints. The yellow-billed cuckoo had HQ_{NOAEL} values that exceeded 1 for HMW PAHs (19.7), BEHP (4.2), and dioxins/furans (2.7; **Table 6-2, Table 6-58**). However, there is a low probability that yellow-billed cuckoo would be present in the vicinity of the site and, if present, it would not likely be exposed to soil in the Main Plant Area based on the limited availability of suitable habitat. Only 38 observations of the yellow-billed cuckoo have been recorded in the Montana Natural Heritage Program Database for the state of Montana. Recorded observations occurred from May to July (MNHP, 2019). If present in the vicinity of the Site, the yellow-billed cuckoo prefers open woodlands with dense, scrubby understory that provide cover, particularly willow or cottonwood-dominated forest canopies, with water nearby (Hughes, 2015). The Western subspecies that would potentially occur at the Site requires patches of at least 10 hectares (25 acres) of dense, riparian forest with a canopy cover of at least 50 percent in both the understory and overstory (MNHP, 2019). Under current conditions, the Main Plant Area is disturbed habitat that lacks wooded habitat; therefore, suitable habitat to support the yellow-billed cuckoo is not present.

The refined exposure models may also overestimate the potential dose to the yellow-billed cuckoo based on estimates of dietary dose based on terrestrial invertebrates (e.g., earthworms). No dietary information is available specific to Montana, but in other parts of the range, the main diet of the yellow-

billed cuckoo is caterpillars. Other insects, some fruits, and sometimes small lizards, frogs, and bird eggs area also consumed. Thus, the assumption in the wildlife ingestion model that the yellow-billed cuckoo diet consists entirely of terrestrial invertebrates is likely conservative; the soil-to-earthworm pathway typically results in higher exposure doses than other pathways, and the assumption that a target receptor ingests terrestrial invertebrates exclusively rather than a mixture of invertebrates and other food items would result in an overestimation of dose for most constituents. Given that the uptake factors for terrestrial invertebrates in the wildlife ingestion model are based on uptake to earthworms, exposure estimates presented in the BERA likely overestimate exposure relative to more representative dietary items for the yellow-billed cuckoo. Because caterpillars and other documented prey items have much less direct contact with soil than earthworms, they would likely bioaccumulate lower COPEC concentrations from soil.

In summary, because of the low number of records in Montana, the lack of its preferred riparian habitat at the Main Plant Area, and its migratory status, it is highly unlikely that the yellow-billed cuckoo is regularly, if ever, present at the Site in general and in the Main Plant Area specifically. Wildlife ingestion assumptions that assume 100 percent ingestion of earthworms likely overestimate risk. These factors should be considered collectively by risk managers when judging the potential for adverse impacts to this threatened species at the Site.

Potential risks to small range receptors were also noted in the Main Plant Area, particularly in the north-central and southeastern portions of the exposure area where some samples exceeded LOAEL-based benchmarks protective of mammalian receptors with limited home ranges, particularly short-tailed shrew. PAHs were detected at concentrations that were elevated compared to background areas.

Based on these findings, there is some potential for adverse effects to ecological receptors in localized areas of the Main Plant Area under current conditions. However, concern regarding constituents in the Main Plant Area are reduced because of the low quality of habitat in the area under current exposure conditions. The Main Plant Area is located in a disturbed, industrial setting with significant portions of it covered by concrete. Thus, it has poor quality resources that most species require for regular use (i.e., foraging areas, vegetative structure used for nesting or bedding areas and protection from predators, water sources). Specifically, the Main Plant Area does not provide habitat for yellow-billed cuckoo, which requires dense, wooded cover (**Section 3.3.6 and 6.1.1.2**). Therefore, ecological exposure is likely to be reduced or incomplete compared to more natural settings with higher habitat quality. Ecological risks are likely overestimated under current conditions and exposure assumptions for the Main Plant Area due to reduced or incomplete exposure pathways; however, further evaluation of exposure to soils with elevated concentrations in the identified localized areas may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.

6.1.2 Central Landfills Area

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial exposure in the Central Landfills Area.

6.1.2.1 Direct Contact Exposure Estimate

The evaluation of direct contact pathways for terrestrial plants and soil invertebrates exposed to soil within the Central Landfills Area indicates limited potential for adverse ecological effects associated primarily with cyanide, metals, and PAHs. In the 0-0.5-ft and 0.5-2-ft sampling intervals, maximum concentrations of soil COPECs were less than available soil invertebrate LOECs, except for copper (HQ_{LOEC} = 13.7; **Table 6-3**). Maximum concentrations exceeded soil invertebrate NOECs for several metals, with HQ_{NOEC} values ranging from 1.9 for nickel to 90.8 for copper (**Table 6-3**). Maximum concentrations of LMW PAHs (HQ_{NOEC} = 33) and HMW PAHs (HQ_{NOEC} = 27) exceeded NOECs for soil invertebrates (**Table 6-3**). Based on refined EPCs for soil invertebrates, cyanide and metal COPEC concentrations were below NOEC values, except for minor exceedances for copper (HQ_{LOEC} = 1.4). Refined risk estimates for LMW PAHs and HMW PAHs resulted in HQ_{NOEC} = 3.0 (**Table 6-3**); soil invertebrate LOECs for LMW and HMW PAHs were not identified.

For terrestrial plants, maximum concentrations of soil COPECs were less than available LOECs for COPECs, except for copper (HQ_{LOEC} = 14.8; **Table 6-3**). Maximum concentrations exceeded terrestrial plant NOECs for cyanide (HQ_{LOEC} = 2.0) and several metals, with HQ_{NOEC} values ranging from 1.9 for beryllium to 104 for copper (**Table 6-3**). Concentrations of organic COPECs exceeding terrestrial plant NOECs were limited to slight exceedances of 3- and 4-methylphenol (HQ_{NOEC} = 1.5) and dibenzofuran (HQ_{NOEC} = 2.5). Based on refined EPCs, cyanide and metal COPEC concentrations were below NOEC values, except for a minor copper exceedance for (HQ_{LOEC} = 1.5).

The spatial distribution of sampling stations within the Central Landfills Area that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities is illustrated in **Figure 6-3**[3]. Elevated HQ_{NOEC} values for copper were driven by the single result at CFSB-002, which had a concentration of 7,260 mg/kg. This concentration was an order of magnitude greater than the next highest concentration of 721 mg/kg and was nearly two orders of magnitude greater than the mean concentration of copper (81 mg/kg) detected in all Central Landfills Area soil samples. Copper concentrations at other stations within the Central Landfills Area were less than LOECs for terrestrial plants and soil invertebrates. Excluding the anomalous copper result of 7,260 mg/kg, the refined direct contact EPC was 16.74 mg/kg, which is lower than terrestrial plant and soil invertebrate NOEC values and the SO#1 BTV of 17.93 mg/kg. Therefore, this elevated detection is considered anomalous and not representative of exposure within the Central Landfills Area. Barium and manganese exceedances of LOECs for terrestrial plants and soil invertebrates were distributed throughout the Central Landfills Area; however, concentrations of these metals were determined to be comparable to background concentrations in hypothesis testing (Roux, 2019). Exceedances of LOECs for other metals were associated with landfill cover stations CFLP-009 and CFLP-012 near the center of the exposure area within the footprint of the Wet Scrubber Sludge Pond (**Figure 6-3**).

6.1.2.2 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to soil in the Central Landfills Area and used maximum concentrations as the EPCs resulted in HQs exceeding 1 for all receptors except for the long-tailed weasel and the North American wolverine (**Table 6-57**). Exposure to copper, Aroclor 1254, and PAHs resulted in the highest HQs within this exposure area (**Appendix H**).

[3] Samples designated with the prefix CFLP- indicate samples represent landfill cover materials.

The refined food chain model using more realistic assumptions resulted in several constituents having an HQ greater than 1, but only copper (American woodcock, yellow-billed cuckoo), Aroclor 1254 (American woodcock, yellow-billed cuckoo), and HMW PAHs (yellow-billed cuckoo) had HQ_{LOAEL} values that exceeded 1. All HQ_{LOAEL} values were less than 5, however (**Tables 6-4 and 6-58**). For copper, over 85 percent of the dose to the woodcock, and nearly the entire dose to the cuckoo was associated with ingestion of terrestrial invertebrates in their diet. Nearly the entire dose of Aroclor 1254 for the woodcock and the cuckoo, and of HMW PAHs for the cuckoo was also attributable to ingestion of terrestrial invertebrates for these two receptors (**Appendix H**). The yellow-billed cuckoo, which is evaluated using NOAEL endpoints, also had HQ_{NOAEL} values that exceeded 1 for LMW PAHs, BEHP, and dioxins/furans.

Because the refined evaluation considers cumulative doses across multiple exposure areas for large range receptors, it is helpful to also evaluate potential risk associated with an exposure area assuming that 100 percent of exposure originates in that area in order to understand contributions from the target area itself rather than adjacent areas. For the Central Landfills Area, the dose associated with copper, Aroclor 1254, and PAHs in soil associated with risk to the American woodcock and yellow-billed cuckoo and the dose associated with LMW PAHs, BEHP, and dioxins/furans that resulted in HQ_{NOAEL} values slightly greater than 1 for the yellow-billed cuckoo, originate entirely from the Central Landfills Area (**Table 6-59**). Neither copper nor PAHs were determined to be background-related by the background hypothesis testing evaluation performed for this exposure area (Roux, 2019). The EPCs for copper in soil in this exposure area were approximately an order of magnitude greater than the SO#1 BTV of 17.93 mg/kg. However, as discussed in **Section 6.1.2.1**, the single sample with elevated copper that strongly influenced the EPC at this exposure area is considered to be anomalous. To determine the influence of the anomalous sample on the calculated risk estimates for wildlife receptors, a refined EPC for copper was calculated after excluding the elevated concentration of 7,260 mg/kg. The resulting EPC of 16.74 mg/kg was an order of magnitude lower than the EPC with the anomalous sample included, and the NOAEL- and LOAEL-based HQs for all wildlife receptors using this revised EPC were all below 1.

The results of the small range receptor evaluation for the Central Landfills Area are presented in **Figure 6-4**. Several sample locations (CFSB-004, CFLP-009, and CFLP-012) had concentrations exceeding the LOAEL-based benchmark for the short-tailed shrew in the area where the Wet Scrubber Sludge Pond was formerly located. Several other locations in the southern portion of the exposure area (CFSB-227 and CFSB-224) between the Wet Scrubber Sludge Pond and the Main Plant Area also contained concentrations, including Aroclor 1254, exceeding the LOAEL-based benchmark for the short-tailed shrew. Several samples from this portion of the exposure area also had constituents at concentrations exceeding NOAEL, but not LOAEL benchmarks (with the exception of CFSB-002, where the anomalous copper concentration exceeded the LOAEL benchmark) for one or both small range receptors.

6.1.2.3 Risk Characterization

Risk estimates for the Central Landfills Area indicate the limited potential for adverse effects associated with exposure to PAHs and select metals, including copper, in soil within localized areas near the former Wet Scrubber Sludge Pond. The direct contact risk evaluation performed at the Central Landfills exposure area indicates that potential risk to soil invertebrates and terrestrial plants is low. Refined risk estimates for soil invertebrates exceeded NOECs for copper, LMW PAHs, and HMW PAHs; refined risk estimates for terrestrial plants exceeded NOECs for beryllium, copper, manganese, and thallium (**Table 6-3**). Greatest HQ_{LOEC} values for soil invertebrates and terrestrial plants were identified for copper; however, EPCs for copper were driven by a single result at CFSB-002 (7,260 mg/kg); copper

concentrations at other stations within the Central Landfills Area were over two orders of magnitude lower and were less than LOECs for terrestrial plants and soil invertebrates. HQ_{NOEC} values for LMW and HMW PAHs differed by an order of magnitude based on whether they were calculated using the maximum or refined EPCs, indicating that localized stations with elevated PAH concentrations are driving risk estimates (**Table 6-3**).

Wildlife ingestion models indicate the potential for adverse effects associated with exposure to copper, PAHs, and Aroclor 1254 assuming conservative exposure assumptions. Copper in Central Landfills Area soil also resulted in HQ_{LOAEL} values that exceeded 1 for the American woodcock and yellow-billed cuckoo for wildlife ingestion pathways. Hypothetical exposure to Aroclor 1254 (American woodcock, yellow-billed cuckoo), and HMW PAHs (yellow-billed cuckoo), also resulted in HQ_{LOAEL} values greater than 1. The ingestion of terrestrial invertebrate prey items was the critical exposure pathway for all COPECs and receptors. Similar to the direct contact pathways, EPCs for copper and PAHs resulting in elevated doses in the wildlife ingestion models are likely driven by localized stations with elevated concentrations. The greatest concentrations of Aroclor 1254 were associated with stations CFSB-227 and CFSB-224 in the southern portion of the exposure area between the Wet Scrubber Sludge Pond and the Main Plant Area. As noted above, the copper HQ values were driven by the single anomalous high concentration at CFSB-002. The small range receptor evaluation indicated several sample locations (e.g., CFLP-009, CFSB-004, CFLP-012, CFSB-227, CFSB-224) with concentrations exceeding the LOAEL-based soil benchmarks for the short-tailed shrew in the area where the Wet Scrubber Sludge Pond was formerly located and in the southern portion of the exposure area between the Wet Scrubber Sludge Pond and the Main Plant Area.

Because of its threatened status, the yellow-billed cuckoo is evaluated on the basis of NOAEL endpoints. In addition to copper, Aroclor 1254, and Total HMW PAHs, the yellow billed cuckoo had HQ_{NOAEL} values that exceeded 1 for LMW PAHs (1.4), BEHP (2.2), and dioxins/furans (1.1; **Table 6-58**). However, as stated for the Main Plant Area (see **Section 6.1.1.3**), the probability of yellow-billed cuckoo being exposed to COPECs in soil in the Central Landfills Area is low given the infrequent observations of yellow-billed cuckoo in the region and the lack of suitable habitat in the Central Landfills Area. Similar to the Main Plant Area, the Central Landfills Area lacks the open woodlands with dense, scrubby understory that the yellow-billed cuckoo requires. Further, the estimation of dietary dose to the yellow-billed cuckoo based on uptake to earthworms likely overestimates exposure experienced through the ingestion of more representative dietary items (see **Section 6.1.1.3**). Based on the low probability of exposure in the Central Landfills Area and the conservative estimate of dietary COPEC concentrations, HQs for the yellow-billed cuckoo are likely overestimated, particularly when only HQ_{NOAEL} values are considered.

Based on these findings, there is limited potential for adverse effects to ecological receptors exposed to copper, PAHs, and Aroclor 1254 in localized areas of the Central Landfills Area under current conditions. Neither copper nor PAHs were determined to be background-related by the background hypothesis testing evaluation performed for this exposure area. Therefore, copper, PAHs, and Aroclor 1254 were considered to be site-related constituents with the potential to result in adverse effects in localized areas identified within the Central Landfills Area. However, the risk associated with copper exposure was strongly influenced by a single highly elevated concentration that is considered to be anomalous. All wildlife receptor HQs were below 1 using an EPC that was calculated with the anomalous concentration excluded. Also, the potential for adverse effects associated with COPECs in soil in the Central Landfills Area is limited because of the low quality of habitat in the area that reduces receptor use and exposure. The Central Landfills Area is located in an industrial setting that has poor quality resources that most species require for regular use (i.e., foraging areas, vegetative structure used for

nesting or bedding areas and protection from predators, water sources). Specifically, the Central Landfills Area does not provide habitat for yellow-billed cuckoo, which require dense, wooded cover (**Section 3.3.6**). Ecological risks are likely overestimated under current conditions and exposure assumptions for the Central Landfills Area due to reduced or incomplete exposure pathways; however, further evaluation of exposure to soils with elevated concentrations in the identified localized areas may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.

6.1.3 Incremental Soil Sampling Grid

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial exposure in the ISS Grid. The ISS Grid is located primarily in the Central Landfills Area, with a portion of the DUs in the northern portion of the Main Plant Area (**Figure 4-8**).

6.1.3.1 Direct Contact Risk Estimate

The evaluation of direct contact pathways for terrestrial plants and soil invertebrates exposed to soil within the ISS Grid was performed using the upper RSD-adjusted EPCs (see **Section 4.1.1.1**). The results indicate limited potential for adverse ecological effects associated primarily with cyanide, metals, and PAHs. Maximum concentrations of soil COPECs were lower than available soil invertebrate LOEC values, except for copper (HQ_{LOEC} = 1.9) and zinc (HQ_{LOEC} = 2.1; **Table 6-5**). Maximum concentrations exceeded soil invertebrate NOECs for arsenic, copper, manganese, mercury, selenium, and zinc, with HQ_{NOEC} values ranging from 2.0 (manganese) to 16.2 (zinc; **Table 6-5**). Maximum concentrations of LMW PAHs (HQ_{NOEC} = 129.9) and HMW PAHs (HQ_{NOEC} = 112..5) exceeded NOECs for soil invertebrates (**Table 6-5**); soil invertebrate LOECs for LMW and HMW PAHs were not identified.

Maximum concentrations of soil COPECs exceeded terrestrial plant LOECs for barium (HQ_{LOEC} = 1.3), copper (HQ_{LOEC} = 2.0), lead (HQ_{LOEC} = 1.1), selenium (HQ_{LOEC} = 5.3), zinc (HQ_{LOEC} = 2.4; **Table 6-5**) and dibenzofuran (HQ_{LOEC} = 1.5). Maximum concentrations exceeded terrestrial plant NOECs for cyanide (HQ_{LOEC} = 4.0) and several metals, with HQ_{NOEC} values ranging from 1.1 for cobalt to 30.7 for selenium (**Table 6-5**). The maximum concentration of dibenzofuran (HQ_{NOEC} = 15.3) also exceeded the terrestrial plant NOEC. 2,4-Dimethyphenol exceeded its terrestrial plant NOEC (HQ_{NOEC} = 71), but a terrestrial plant LOEC was not identified for this compound, and it was only detected in two ISS samples at a maximum concentration of 0.7 mg/kg (**Table 6-5**).

Figure 6-5 illustrates the spatial distribution of sampling stations within the ISS Grid that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. The upper, measured, and lower RSD adjusted EPCs are represented by the three rows of results in the figure (because the four ISS grid areas with triplicate samples (CFISS-01, -04, -011, and -015) have EPCs based on calculated UCL_{mean} values rather than RSD adjusted concentrations, they have identical results for the three rows). Barium concentrations are likely associated with background soil conditions. Barium concentrations that exceed terrestrial plant LOECs were lower than or approximated the BTV (299.5 mg/kg) calculated for similar background soil type (SO#1); further, barium concentrations in surface soils from the Main Plant Area and Central Landfills Area that encompasses the ISS Grid were determined to be comparable to background concentrations in hypothesis testing (Roux, 2019). Exceedances of selenium were identified

in contiguous DUs in the eastern portion of the ISS Grid, and exceedances of zinc were identified in two contiguous DUs in the southwestern corner of the ISS Grid (**Figure 6-5**).

6.1.3.2 Ingestion Risk Estimate

As discussed in **Section 4.1.1.1**, the Incremental Soil Sampling Grid was not included in the wildlife ingestion model. Potential risks to small-range receptors were evaluated using the point-by-point comparison to ESVs protective of the meadow vole and short-tailed shrew, as discussed below.

The results of the small range receptor evaluation for the Incremental Sampling Grid within the Operational Area are presented in **Figure 6-6**, which uses a similar 2-by-3 grid as **Figure 6-5** to depict exceedances for the short-tailed shrew and meadow vole across the three EPCs for each DU. Incremental samples in all DUs exceeded a NOAEL-based benchmark for at least one of the two evaluated small range receptors. Exceedances of the LOAEL-based benchmarks were limited to the southeastern (CFISS-033 and -044), north-central (CFISS-007, -011, -012, -013, and -020) and northwest-central (CFISS-003 and -004) DUs. All exceedances were associated with the short-tailed shrew receptor, except for CFISS-013, which also exceeded LOAEL-based benchmarks for the meadow vole. Exceedances of LOAEL-based benchmarks for short-tailed shrew were primarily associated with LMW and HMW PAH exposures. Several DUs located in the center of the Operational Area also had PCB-1254 concentrations that exceeded LOAEL-based benchmarks for the short-tailed shrew (**Figure 6-6**).

6.1.3.3 Risk Characterization

Risk estimates for the ISS Grid were similar to risk estimates for overlapping areas within the Main Plant Area and Central Landfills Area. Direct contact exposure to soil invertebrates was greatest for PAHs and select metals, including copper and zinc. The greatest exposure to terrestrial plants was associated with exposure to selenium, copper, and zinc. However, risk estimates based on maximum EPCs resulted in $HQ_{LOEC} < 5$ (when rounded) for terrestrial plants and soil invertebrates.

Effects associated with wildlife ingestion pathways were evaluated for the ISS Grid using comparisons of NOAEL- and LOAEL-based benchmarks for small range receptors to EPCs estimated for individual DUs. Several of the DUs, particularly in the central third of the ISS Grid within the Central Landfills Area, had concentrations of constituents that exceeded LOAEL-based benchmarks protective of small range receptors. Exceedances of LOAEL-based benchmarks in these DUs were primarily associated with LMW and HMW PAH exposure to the short-tailed shrew. Exposure to Aroclor 1254 also resulted in LOAEL-based exposure to the short-tailed shrew in five of these DUs.

Because of the exceedances of LOEC/LOAEL benchmarks, there is some potential for adverse effects associated with exposure to copper, selenium, and PAHs in soil in select DUs. However, because the exceedances were relatively low, risk is considered moderate. PAHs in soil may also represent a risk to ecological receptors, particularly soil invertebrates. However, because of the lack of LOEC values, the potential risk to these receptors is an uncertainty. PAHs were found to be elevated relative to background in the hypothesis testing evaluation performed for the Central Landfills and Main Plant exposure areas, which overlap the ISS Grid. Similar to the Main Plant Area and Central Landfills Area, concern regarding exposure to COPECs in the ISS Grid are reduced because of the low quality of habitat in the area. The ISS Grid is located in an industrial setting with poor habitat quality and limited resources that are required by most species for regular use. Ecological risks are likely overestimated under current conditions and exposure assumptions for the ISS Grid due to reduced or incomplete exposure pathways;

however, further evaluation of exposure to soils with elevated concentrations in the identified DUs may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.

As described in **Sections 5.3.1** and **6.1.3.3**, soil EPCs based on individual DUs within the Operational Area ISS sampling grid were compared to benchmark values protective of small range receptors that would be expected to obtain their entire exposure within the approximately 1-acre sized DUs. Discrete soil samples that were also collected from within the ISS grid as part of the broader Site characterization effort were pooled with other discrete samples from the Main Plant Area or Central Landfills Area, which are the two exposure areas that overlap the Operational Area. The discrete soil sample dataset was used to evaluate potential risks associated with direct contact and indirect/food chain effects for a variety of receptors selected to represent the trophic positions of ecological species likely to be present. Discrete samples across the Site were also individually compared to calculated benchmark concentrations protective of small-range receptors (i.e., the meadow vole and short-tailed shrew).

As stated in the BERA Work Plan (EHS Support, 2018) and *Technical Memorandum: Proposed Wildlife Exposure Modeling Approach to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site* presented in **Appendix A2**, exposure to receptors with moderately sized home ranges that may forage within multiple, adjacent DUs within the ISS grid was not quantified. This results in some uncertainty regarding potential risk to receptors with home ranges larger than an acre but smaller than the 43-acre Operational Area, including the American woodcock (11.1 acre home range), yellow-billed cuckoo (42 acre home range), and the long-tailed weasel (12 acre home range) that may forage exclusively within the Operational Area.

The uncertainty regarding the lack of evaluation of mid-range receptors is reduced based on the evaluation of relative exposure to small range receptor exposure and habitat quality within the Operational Area. HQs for small range receptors are typically higher than larger range receptors, owing to the fact that small range receptors (such as the meadow vole and short-tailed shrew) are smaller in size and have a higher relative metabolic/ingestion rate (and, therefore, calculated constituent dose) per unit body weight than larger species within the same foraging guild (USEPA, 2005b). Thus, evaluations and conclusions protective of small home range receptors are likely also protective of larger range receptors. The analysis of concentrations present at each DU and the comparison to NOAEL-based and LOAEL-based benchmark values for the meadow vole (herbivore) and short-tailed shrew (insectivore) presented in Section 6.1.3.2 indicated that most DUs within the Operational Area had constituent concentrations that were below LOAEL-based benchmarks, but 10 ISS locations primarily within the center of the sampling grid had concentrations that exceeded LOAEL-based benchmarks. Although one of the mid-range receptors of concern (the long-tailed weasel) is a carnivore, which is a foraging guild not represented by the two species used to develop wildlife benchmarks for the point-by-point analysis, and another (the yellow-billed cuckoo) is an avian species that may have somewhat different toxicity thresholds than the mammalian small-range receptors upon which the small-range receptor benchmarks were developed, risk management decisions based upon small body weight herbivores and insectivores are likely to also be protective of these receptors with mid-sized home ranges. This is supported by the fact that the mammalian insectivore exposure pathway (represented by the short-tailed shrew) typically results in the highest dose among wildlife receptors. Also, the home ranges of two of the three mid-range receptors listed above are approximately double the size of the six 1-acre DUs where LOAEL-based benchmarks were exceeded, and the third (the yellow-billed cuckoo) approximates the size of the entire Operational Area. Therefore, some dilution of dose based on exposure to less contaminated areas would result in a lower expected likelihood of adverse effects to

the three mid-range receptors of concern compared to the 1-acre exposure areas assumed for the short-tailed shrew and meadow vole.

A second consideration that reduces the uncertainty for mid-range receptors is that the Operational Area is in an area that was highly disturbed by plant operations and lacks sufficient habitat to sustain 100 percent of the foraging requirements of mid-range receptors. Habitat qualities favored by the evaluated mid-range receptors such as forest thickets (American woodcock), seral ecotones and forests with openings (long-tailed weasel), and dense, riparian forest with canopy cover of at least 50 percent (yellow-billed cuckoo) are absent in this portion of the Site. Therefore, the potential for the occurrence of such receptors is low. Although irregular exposure may occur, it is unlikely that the habitat present in this area would support multiple individuals foraging 100 percent of the time within the Operational Area. Thus, the potential for adverse effects to populations associated with the receptor groups represented by the American woodcock and long-tailed weasel, is highly unlikely due to the absence of a sufficient forage base to sustain populations of these receptor groups. The yellow-billed cuckoo is a threatened species that is protected on the individual level. However, as stated previously for the Main Plant Area and Central Landfills Area, there is low probability of yellow-billed cuckoo to be present in the vicinity of the Site is due to its rarity in Montana in general, and an even lower probability of occurrence within the Operational Area due to the absence of basic habitat requirements (see **Section 6.1.1.3**).

Based on the information presented in the preceding paragraphs, it is unlikely that the lack of evaluation of receptors with mid-sized home ranges within the Operational Area represents a significant uncertainty in the BERA. Risk management decisions based on the sessile and small-range receptors that are currently the focus of evaluation in this area are likely to be protective of larger-ranging receptors as well.

6.1.4 Industrial Landfill Area

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial exposure in the Industrial Landfill Area.

6.1.4.1 Direct Contact Risk Estimate

The evaluation of direct contact pathways for terrestrial plants and soil invertebrates exposed to soil within the Industrial Landfill Area indicates limited potential for adverse ecological effects associated primarily with PAHs and select metals. In the 0-0.5-ft and 0.5-2-ft sampling intervals, maximum concentrations of soil COPECs were less than available soil invertebrate LOECs; however, soil invertebrate LOECs for PAHs were not identified (**Table 6-6**). Maximum concentrations exceeded soil invertebrate NOECs for arsenic (HQ_{NOEC} = 3.5), nickel (HQ_{NOEC} = 1.7), and LMW (HQ_{NOEC} = 7.0) and HMW PAHs (HQ_{NOEC} = 13.4; **Table 6-6**). Refined risk estimates for soil invertebrates potentially exposed to arsenic, nickel, and LMW and HMW PAHs resulted in similar HQ_{NOEC} values to maximum EPCs.

For terrestrial plants, maximum concentrations of soil COPECs were less than available LOECs, except for nickel and vanadium (HQ_{LOEC} = 1.7 and HQ_{LOEC} = 2.1, respectively; **Table 6-6**). Maximum concentrations exceeded terrestrial plant NOECs for several metals, with HQ_{NOEC} values ranging from 1.3 for arsenic to 12.2 for nickel (**Table 6-6**). Refined EPCs were below terrestrial plant LOECs, except for minor exceedances for nickel (HQ_{LOEC} = 1.5) and vanadium (HQ_{LOEC} = 1.9).

Figure 6-7[4] illustrates the spatial distribution of sampling stations within the Industrial Landfill Area that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. Direct contact LOEC exceedances were associated with maximum concentrations observed at station CFLP-005; concentrations at other Industrial Landfill Area stations were less than LOECs.

6.1.4.2 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to soil in the Industrial Landfill Area and used maximum concentrations as the EPCs resulted in HQs exceeding 1 for multiple receptors (**Table 6-57**). Exposure to PAHs resulted in the highest HQs within this exposure area (**Appendix H**).

The refined food chain model using more realistic assumptions resulted in several constituents having an HQ greater than 1, but only nickel (American woodcock and short-tailed shrew) and HMW PAHs (American woodcock and yellow-billed cuckoo) had HQ_{LOAEL} values that exceeded 1 (**Tables 6-7 and 6-58**). All HQ_{LOAEL} values were less than 5, however. For nickel, approximately 90 percent of the dose to the woodcock and 99 percent of the dose to the shrew was associated with ingestion of terrestrial invertebrates. For HMW PAHs, approximately 94 percent of the dose to the woodcock and nearly the entire dose to the yellow-billed cuckoo was associated with ingestion of terrestrial invertebrates. The yellow-billed cuckoo, which is evaluated using NOAEL endpoints, also had an HQ_{NOAEL} value that exceeded 1 for nickel (2.3; **Tables 6-7** and **6-58**).

Because the refined evaluation considers cumulative doses across multiple exposure areas for large range receptors, it is helpful to also evaluate potential risk associated with an exposure area assuming that 100 percent of exposure originates in that area in order to understand contributions from the target area itself rather than adjacent areas. For the Industrial Landfill Area, the doses associated with nickel and PAHs in soil associated with risk to the American woodcock and yellow-billed cuckoo originate primarily from the Industrial Landfill Area (**Table 6-59**). Furthermore, neither nickel nor PAHs were determined to be background-related in the background hypothesis testing evaluation at this exposure area (Roux, 2019). Therefore, nickel and PAHs in soil at the Industrial Landfill Area represent a moderate risk to ecological receptors due to exposure from direct and indirect ingestion pathways.

The results of the small range receptor evaluation for the Industrial Landfill Area are presented in **Figure 6-8**. None of the four soil sample locations in the center and southwestern portion of the area had concentrations that exceeded LOAEL benchmarks. Both sample locations in the northeastern portion of the site (CFLP-005 and CFLP-006) had concentrations that exceeded NOAEL-based benchmarks for the meadow vole (HMW PAHs and nickel) and LOAEL benchmarks for the short-tailed shrew (HMW PAHs).

6.1.4.3 Risk Characterization

Risk estimates for the Industrial Landfill Area indicate the limited potential for adverse effects associated with exposure to PAHs and select metals in soil. Refined risk estimates for soil invertebrates exceeded NOECs for arsenic, nickel, LMW PAHs, and HMW PAHs; refined risk estimates for terrestrial plants exceeded NOECs for five metals (**Table 6-6**). The evaluation of direct contact pathways for soil invertebrates exposed to soil within the Industrial Landfill Area indicates the greatest potential for adverse effects is associated with exposure to LMW and HMW PAHs based on HQ_{NOEC} values; however,

[4] Samples designated with the prefix CFLP- indicate samples represent landfill cover materials.

the absence of soil invertebrate LOECs results in some uncertainty in the risk estimate. Direct contact impacts associated with soil constituents to terrestrial plants are expected to be low, due to no or very minor exceedances of terrestrial plant LOECs.

The results of the food chain model indicated that nickel (American woodcock and short-tailed shrew) and HMW PAHs (American woodcock and yellow-billed cuckoo) had HQ_{LOAEL} values that exceeded 1 in this exposure area. All HQ_{LOAEL} values were less than 5, however. Neither nickel nor PAHs were determined to be background-related. Also, two sample locations in the northeastern portion of the site exceeded LOAEL-based soil benchmarks for small range receptors. The ingestion of terrestrial invertebrate prey items was the critical exposure pathway for both nickel (American woodcock and short-tailed shrew, and the yellow-billed cuckoo when evaluated using the an HQ_{NOAEL}) and HMW PAHs (American woodcock and yellow-billed cuckoo). Therefore, nickel and PAHs in soil at the Industrial Landfill Area represent a moderate risk to ecological receptors due to exposure from direct and indirect ingestion pathways. Risk associated with nickel were driven by two highly elevated concentrations, both of which were in soil boring CFLP-005, which is in the northeastern portion of the exposure area. The concentration of nickel in the 0 to 0.5 ft sample at this location was 463 mg/kg and was 513 mg/kg in the 0.5 to 2 ft sample. Six additional soil samples exceeded the nickel BTV of 17.32 mg/kg in this exposure area as well. All other samples were below 100 mg/kg. Elevated HMW PAHs were also detected in CFLP-005 (0 to 0.5 ft) as well as CFLP-006 (0 to 0.5 ft), which is approximately 250 feet to the northwest of CFLP-005. Concentrations in these samples were over 100 mg/kg, at 166.6 mg/kg and 388 mg/kg, respectively. The deeper sample from CFLP-005 (0.5 to 2 ft) (91.2 mg/kg) and CFLP-003 (0.5-2 ft) (99 mg/kg) were also somewhat elevated (i.e., greater than 50 mg/kg). All other concentrations were below 50 mg/kg. Concern regarding COPEC exposure in the Industrial Landfill Area are reduced because of the disturbed and low quality of habitat in the area. The Industrial Landfill Area is a waste disposal area with limited resource qualities relative to more naturalized adjacent habitats. Due to the reasons stated in **Section 6.1.1.3**, the HQs for the cuckoo are likely overestimated based on the limited probability of occurrence of this species and the conservative estimate of dietary COPEC concentrations, particularly when only HQ_{NOAEL} values are considered. Specifically, the Industrial Landfill Area does not provide habitat for yellow-billed cuckoo, which require dense, wooded cover (**Section 3.3.6**). Ecological risks are likely overestimated under current conditions and exposure assumptions for the Industrial Landfill Area due to reduced or incomplete exposure pathways. It is also noted that the Industrial Landfill Area is uncapped. As such, the concentrations of COPECs may be reflective of the waste materials disposed of within the landfill.

6.1.5 Eastern Undeveloped Area

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial exposure in the Eastern Undeveloped Area.

6.1.5.1 Direct Contact Risk Estimate

The evaluation of direct contact pathways for terrestrial plants and soil invertebrates exposed to soil within the Eastern Undeveloped Area indicates negligible potential for adverse ecological effects associated with select metals. In the 0-0.5-ft and 0.5-2-ft sampling intervals, maximum concentrations of soil COPECs were less than soil invertebrate LOECs available for COPECs (**Table 6-8**). Maximum concentrations exceeded soil invertebrate NOECs for five metals, with HQ_{NOEC} values ranging from 1.3 for

zinc to 8.8 for manganese (**Table 6-8**). Based on refined EPCs, metal COPEC concentrations were below soil invertebrate NOEC values, except for barium (HQ_{LOEC} = 1.8) and manganese (HQ_{LOEC} = 3.2).

For terrestrial plants, maximum concentrations of soil COPECs were less than available LOECs, except for barium and manganese (HQ_{LOEC} = 4.1 and HQ_{LOEC} = 3.6, respectively; **Table 6-8**). Maximum concentrations exceeded terrestrial plant NOECs for five metals, with HQ_{NOEC} values ranging from 1.2 for selenium to 18 for manganese (**Table 6-8**). Refined EPCs were below terrestrial plant LOECs, except for minor exceedances for barium (HQ_{LOEC} = 2.2) and manganese (HQ_{LOEC} = 1.3; **Table 6-8**).

Figure 6-9 illustrates the spatial distribution of sampling stations within the Eastern Undeveloped Area that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. Exceedances of barium and manganese on the eastern boundary of the Eastern Undeveloped Area were comparable to the BTVs calculated for barium (774 mg/kg) and manganese (1,566 mg/kg) for background soil area SO#4 that is typical of the Revett Formation soil type at the base of Teakettle Mountain (Roux, 2019). Exceedances to the west of the Cedar Creek Overflow Ditch are comparable to BTVs for barium (300 mg/kg) and manganese (1,566 mg/kg) calculated for the background soil area SO#1, which is representative of most of the developed portion of the Site (**Figure 6-9**). These findings indicate that direct contact exposure to barium and manganese are consistent with background exposure in the Eastern Undeveloped Area.

6.1.5.2 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to soil in the Eastern Undeveloped Area and used maximum concentrations as the EPCs resulted in HQ_{NOAEL} values exceeding 1 for four receptors (**Table 6-57**). However, all values were less than 5, and no HQ_{LOAEL} values exceeded 1 (**Appendix H**).

The refined food chain model using more realistic assumptions resulted in two constituents having an HQ_{NOAEL} greater than 1 including nickel for the short-tailed shrew and BEHP (HQ =1.2) for the yellow-billed cuckoo (**Tables 6-9 and 6-58**). Neither of these HQ_{NOAEL} values were greater than 1 when rounded, and HQ_{LOAEL} values were less than 1. BEHP is also a common laboratory contaminant and is unlikely related to previous Site activities. Therefore, nickel and BEHP in soil at the Eastern Undeveloped Area represent a minimal risk to ecological receptors due to exposure from direct and indirect ingestion pathways.

The results of the small range receptor evaluation for the Eastern Undeveloped Area indicate that COPEC concentrations are below LOAEL-based benchmarks for meadow vole and short-tailed shrew at all sampling locations (**Figure 6-10)**. Stations along the eastern boundary of the Eastern Undeveloped Area and within the Borrow Pit Area exceed NOAEL-based benchmarks for nickel for short-tailed shrew, with a maximum HQ of 1.7. All sampling locations were below NOAEL-based benchmarks for the meadow vole.

6.1.5.3 Risk Characterization

Risk estimates for the Eastern Undeveloped Area indicate minimal potential for adverse effects associated with exposure to soil. Refined risk estimate indicates minor NOEC exceedances for soil invertebrates (barium and manganese) and terrestrial plants (barium, manganese, nickel, and thallium; **Table 6-8**). However, risks to soil invertebrates and terrestrial plant communities are considered to be

negligible relative to background risk in the Eastern Undeveloped Area. Maximum concentrations for all constituents were below LOEC benchmarks for soil invertebrates, and refined EPCs for barium and manganese, which were detected at concentrations comparable to background, only marginally exceeded LOEC benchmarks for plants.

The wildlife ingestion model indicated that no HQ_{NOAEL} values exceeded 1 when rounded and all HQ_{LOAEL} values were less than 1 for all receptors. The estimated dose of BEHP for yellow-billed cuckoo slightly exceeded the NOAEL (HQ = 1.2; **Table 6-9**). Although the yellow-billed cuckoo is evaluated based on NOAEL endpoints due to its current status as a federally threatened species, the likelihood of adverse effects resulting from exposure to BEHP is low. As previously discussed, there is a low probability of occurrence of yellow-billed cuckoo at the Site and the dose that slightly exceeded the NOAEL TRV was based on the conservative estimate of dietary COPEC concentrations based on 100 percent ingestion of earthworms that likely overestimates COPEC concentrations in dietary items associated with the yellow-billed cuckoo (see **Section 6.1.1.3**). The small-range receptor evaluation did not identify any sample locations that exceeded LOAEL-based benchmarks. Therefore, the potential for ecological risk at the Eastern Undeveloped Area is expected to be minimal.

6.1.6 North-Central Undeveloped Area

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial exposure in the North-Central Undeveloped Area.

6.1.6.1 Direct Contact Risk Estimate

The evaluation of direct contact pathways for terrestrial plants and soil invertebrates exposed to soil within the North-Central Undeveloped Area indicates negligible potential for adverse ecological effects associated with select metals. Maximum concentrations of soil COPECs were less than soil invertebrate available LOECs (**Table 6-10**). Maximum concentrations exceeded soil invertebrate NOECs for arsenic (HQ_{NOEC} = 2.3), barium (HQ_{NOEC} = 1.5), and manganese (HQ_{NOEC} = 5.8; **Table 6-10**). Based on refined EPCs, metal COPEC concentrations were below soil invertebrate NOEC values, except for barium (HQ_{LOEC} = 2.5).

For terrestrial plants, maximum concentrations of soil COPECs were lower than available LOECs, except for a minor barium exceedance (HQ_{LOEC} = 1.9; **Table 6-10**). Maximum concentrations exceeded terrestrial plant NOECs for three metals, with HQ_{NOEC} values ranging from 3.8 for thallium to 11.9 for manganese (**Table 6-10**). Refined EPCs were below terrestrial plant LOECs, except for a slight exceedance for barium (HQ_{LOEC} = 1.1 **Table 6-10**).

Figure 6-11 illustrates the spatial distribution of sampling stations within the North-Central Undeveloped Area that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. Exceedances of soil invertebrate or terrestrial plant LOECs are limited to barium and manganese. Manganese concentrations were determined to be comparable to background concentrations in hypothesis testing between the approximate portion of the site encompassed by the North-Central Undeveloped Area and background sampling area SO#1 (Roux, 2019). Exceedances of barium on the eastern boundary of the North-Central Undeveloped Area were less than the BTV calculated for barium (774 mg/kg) for background soil area SO#4 that is typical of the Revett Formation soil type at the base of Teakettle Mountain (Roux, 2019). Barium exceedances to the west of the Cedar Creek Reservoir Overflow Ditch (**Figure 6-11**) are generally comparable to BTV for barium (300 mg/kg)

calculated for the background soil area SO#1. These findings indicate that direct contact exposure to barium and manganese are consistent with background exposure in the North-Central Undeveloped Area.

6.1.6.2 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to soil in the North-Central Undeveloped Area and used maximum concentrations as the EPCs resulted in HQ_{NOAEL} values exceeding 1 for cyanide (American woodcock, mourning dove, and yellow-billed cuckoo) and BEHP (American woodcock, yellow-billed cuckoo) (**Table 6-57**). However, no HQ_{NOAEL} values exceeded 5, and no HQ_{LOAEL} values exceeded 1 (**Appendix H**).

The refined food chain model using more representative exposure assumptions resulted in HMW PAHs having an HQ greater than 1 for the mourning dove (1.5; **Tables 6-11 and 6-58**). All HQ_{LOAEL} values were less than 1. Because the refined evaluation considers cumulative doses across multiple exposure areas for large range receptors, it is helpful to also evaluate potential risk associated with an exposure area assuming that 100 percent of exposure originates in that area in order to understand contributions from the target area itself rather than adjacent areas. For the North-Central Undeveloped Area, the dose associated with PAHs in soil associated with risk to the mourning dove does not originate from the North-Central Undeveloped Area, as all HQs are below 1 for these constituents when only doses from the target exposure area are considered (**Table 6-59**). Therefore, no constituents in soil at the North-Central Undeveloped Area represent a significant risk to ecological receptors due to exposure from direct and indirect ingestion pathways.

The results of the small range receptor evaluation for the North-Central Undeveloped Area are presented in **Figure 6-12**. All soil sample locations in this exposure area were below NOAEL-based benchmarks for small range receptors. It is noted that this ecological exposure area includes the sample locations around the periphery of the Industrial Landfill exposure area, indicating that the soil surrounding the landfill does not pose a threat to small range mammalian receptors.

6.1.6.3 Risk Characterization

Risk estimates for the North-Central Undeveloped Area indicate minimal potential for adverse effects associated with exposure to soil. Negligible risks to soil invertebrates and terrestrial plant communities above background risk are expected in the North-Central Undeveloped Area. Maximum concentrations for all constituents were below LOEC benchmarks for invertebrates, and refined EPCs for barium and manganese, which were detected at concentrations comparable to background, only marginally exceeded NOEC and LOEC benchmarks for plants. The wildlife ingestion model indicated that all HQ_{NOAEL} and HQ_{LOAEL} values were less than 1 for all receptors when only contributions from the North-Central Undeveloped Area were included in the risk estimates, and the small-range receptor evaluation did not identify any sample locations that exceeded LOAEL-based benchmarks. Therefore, the potential for ecological risk at the North-Central Undeveloped Area is expected to be minimal.

6.1.7 Western Undeveloped Area

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial exposure in the Western Undeveloped Area.

6.1.7.1 Direct Contact Risk Estimate

The evaluation of direct contact pathways for terrestrial plants and soil invertebrates exposed to soil within the Western Undeveloped Area indicates negligible potential for adverse ecological effects associated with select metals. Maximum concentrations of soil COPECs were less than available soil invertebrate LOECs available for COPECs (**Table 6-12**). Maximum concentrations exceeded soil invertebrate NOECs for four metals, with HQ_{NOEC} values ranging from 1.6 (barium) to 4.9 (manganese; **Table 6-12**). Based on refined EPCs, metal COPEC concentrations were below soil invertebrate NOEC values, except for manganese (HQ_{LOEC} = 1.4).

For terrestrial plants, maximum concentrations of soil COPECs were lower than available LOECs, except for barium (HQ_{LOEC} = 2.1) and manganese (HQ_{LOEC} = 2.0; **Table 6-12**). Maximum concentrations exceeded terrestrial plant NOECs for four metals, with HQ_{NOEC} values ranging from 1.5 for zinc to 10.0 for manganese (**Table 6-12**). Refined EPCs were below terrestrial plant LOECs, except for a slight exceedance for barium (HQ_{LOEC} = 1.2).

Figure 6-13 illustrates the spatial distribution of sampling stations within the Western Undeveloped Area that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. Exceedances of soil invertebrate or terrestrial plant LOECs are limited to barium and manganese. Manganese concentrations were determined to be comparable to background concentrations in hypothesis testing between the approximate portion of the site encompassed by the Western Undeveloped Area and background sampling area SO#1 (Roux, 2019). Barium concentrations that exceeded LOECs ranged from below to within two times the BTV (300 mg/kg) calculated for the background soil area SO#1 (**Figure 6-13**). These findings indicate that direct contact exposure to barium and manganese do not represent a substantial incremental risk above background risk.

6.1.7.2 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to soil in the Western Undeveloped Area and used maximum concentrations as the EPCs resulted in HQ_{NOAEL} values exceeding 1 for four receptors (**Table 6-57**). However, all values were less than 5, and no HQ_{LOAEL} values exceeded 1 (**Appendix H**).

The refined food chain model using more realistic assumptions resulted in two constituents having an HQ greater than 1, including HMW PAHs for the mourning dove (HQ_{NOAEL} =1.5) and dioxins/furans for the short-tailed shrew (HQ_{NOAEL} =1.1); **Tables 6-13 and 6-58**). No HQ_{LOAEL} values exceeded 1.

Because the refined evaluation considers cumulative doses across multiple exposure areas for large range receptors, it is helpful to also evaluate potential risk associated with an exposure area assuming that 100 percent of exposure originates in that area in order to understand contributions from the target area itself rather than adjacent areas. For the Western Undeveloped Area, the dose associated with PAHs in soil associated with risk to the mourning dove does not originate from the Western Undeveloped Area, as all HQs are below 1 for these constituents when only doses from the target exposure area are considered (**Table 6-59**). The risk to the shrew associated with dioxin/furans does originate from the Western Undeveloped Area. However, because the HQs are so low (equal to or below 1, when rounded, for both the HQ_{NOAEL} and HQ_{LOAEL}), the risk associated with dioxins in soil is considered

minimal. Therefore, no constituents in soil at the Western Undeveloped Area represent a significant risk to ecological receptors due to exposure from direct and indirect ingestion pathways.

The results of the small range receptor evaluation for the Western Undeveloped Area are presented in **Figure 6-14**. With the exception of one sample location (CFSB-216) that had concentrations exceeding the NOAEL-based benchmark for the short-tailed shrew for $TEC_{2,3,7,8\text{-}TCDD}$, all soil sample locations in this exposure area were below NOAEL-based benchmarks for small range receptors.

6.1.7.3 Risk Characterization

Risk estimates for the Western Undeveloped Area indicate minimal potential for adverse effects associated with exposure to soil. Negligible risks above background risks are expected for soil invertebrates and terrestrial plant communities in the Western Undeveloped Area. Refined risk estimates only slightly exceeded the NOEC for manganese for soil invertebrates (HQ = 1.4) and barium (HQ = 2.8) and manganese (HQ = 2.8) for terrestrial plants **Table 6-12**).Maximum concentrations for all constituents were below LOEC benchmarks for invertebrates, and refined EPCs for barium and manganese only marginally exceeded LOEC benchmarks for plants. Manganese and barium concentrations were generally comparable to background concentrations, indicating that incremental risk above background is not substantial. The wildlife ingestion model indicated that all HQ_{NOAEL} and HQ_{LOAEL} values attributable to the exposure area were equal to or less than 1 for all receptors when rounded and the small-range receptor evaluation did not identify any sample locations that exceeded LOAEL-based benchmarks. Therefore, the potential for ecological risk at the Western Undeveloped Area is expected to be minimal.

6.1.8 Flathead River Riparian Area

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial exposure in the Flathead River Riparian Area.

6.1.8.1 Direct Contact Risk Estimate

The evaluation of direct contact pathways for terrestrial plants and soil invertebrates exposed to soil within the Flathead River Riparian Area indicates negligible potential for adverse ecological effects. Maximum concentrations of soil COPECs were less than soil invertebrate ESVs for all COPECs. The maximum arsenic concentration was the only COPEC concentration to exceed soil invertebrate NOECs (HQ_{NOEC} = 1.2; **Table 6-14**). Based on refined EPCs, metal COPEC concentrations were below soil invertebrate NOEC values.

For terrestrial plants, maximum concentrations of soil COPECs were less than LOECs for COPECs, except for minor exceedances of barium (HQ_{NOEC} = 1.4) and manganese (HQ_{NOEC} = 1.6). Maximum concentrations exceeded terrestrial plant NOECs for barium (HQ_{NOEC} = 2.1) and manganese (HQ_{NOEC} = 2.1). Refined EPCs exceeded terrestrial plant NOECs for barium (HQ_{NOEC} = 1.4) and manganese (HQ_{NOEC} = 1.6); refined EPCs were below terrestrial plant LOECs (**Table 6-14**).

Figure 6-15 illustrates the spatial distribution of sampling stations within the Flathead River Riparian Area that exceed direct contact NOECs for soil invertebrate or terrestrial plant communities. As described above, soil concentrations were below available LOECs for terrestrial plants and soil

invertebrates. Arsenic and manganese slightly exceeded soil invertebrate NOECs at stations CFSB-142 and CFSB-141, respectively. Exceedances at remaining stations are associated with concentrations exceeding terrestrial plant NOECs for barium or manganese, which are comparable to background soil concentrations. Manganese concentrations were determined to be comparable to background concentrations in hypothesis testing between the approximate portion of the site encompassed by the Flathead River Riparian Area and background sampling areas SO#2 and SO#3 (Roux, 2019). The maximum barium concentration in soil in the Flathead River Riparian Area (236 mg/kg) is below the BTV calculated for similar alluvial deposit background soil areas SO#2 and SO#3 (300 mg/kg; Roux, 2019). These findings indicate that direct contact exposure to barium and manganese do not represent a substantial incremental risk above background risk.

6.1.8.2 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to media in the Flathead River Riparian Area and used maximum concentrations as the EPCs resulted in HQ_{NOAEL} values exceeding 1 for three receptors due to exposure to cyanide (**Table 6-57**). However, all values were less than 5, and no HQ_{LOAEL} values exceeded 1 (**Appendix H**).

The refined food chain model using more realistic assumptions resulted in one exceedance associated with the exposure of the mourning dove to HMW PAHs (HQ_{NOAEL} = 1.5; **Table 6-15 and 6-58**). However, exposure to HMW PAHs is not originating from the Flathead River Riparian Area, as the HQs for these PAHs were below 1 in the screening-level iteration of the food chain models (**Table 6-57)** and the refined exposure area-specific evaluation (**Table 6-59**) which assume 100 percent exposure to the target exposure area. Therefore, COPECs in soil at the Flathead River Riparian Area do not represent a significant risk to ecological receptors due to exposure from direct and indirect ingestion pathways.

The results of the small range receptor evaluation for the Flathead River Riparian Area are presented in **Figure 6-16**. All soil sample locations in this exposure area were below NOAEL benchmarks for small range receptors.

6.1.8.3 Risk Characterization

Risk estimates for the Flathead River Riparian Area indicate minimal potential for adverse effects associated with exposure to soil. Negligible risks to soil invertebrates and terrestrial plant communities are expected in the Flathead River Riparian Area. Refined risk estimates were below direct contact NOECs for soil invertebrates and slightly exceeded NOECs for barium (HQ = 1.4) and manganese (HQ = 1.6). Maximum concentrations for all constituents were below LOEC benchmarks for both soil invertebrates and terrestrial plants. The wildlife ingestion model indicated that all exposure area-specific HQ_{NOAEL} values were less than 1 for all receptors, and the small-range receptor evaluation did not identify any sample locations that exceeded NOAEL- or LOAEL-based benchmarks. Therefore, the potential for ecological risk at the Flathead River Riparian Area is expected to be minimal.

6.2 Transitional Exposure Areas

Risk estimates and baseline risk characterizations for direct contact and ingestion exposure pathways are presented below for transitional exposure areas. Given the seasonably variable hydrology of

transitional exposure areas, direct contact exposure is evaluated for terrestrial receptors based on exposure to soil and for aquatic receptors based on exposure to sediment and surface water.

6.2.1 North Percolation Pond Area

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial and aquatic exposure scenarios in the North Percolation Pond Area.

6.2.1.1 Terrestrial Direct Contact Risk Estimate

The evaluation of direct contact pathways for terrestrial plants and soil invertebrates exposed to soil under dry conditions in the North Percolation Pond indicates the potential for adverse ecological effects, primarily associate with cyanide, metals, and PAHs. Maximum concentrations exceeded soil invertebrate NOECs for several metals, with HQ_{NOEC} values ranging from 2.4 (mercury) to 7.3 (zinc); maximum metal concentrations were lower than available LOECs for soil invertebrates (**Table 6-16**). Maximum concentrations of LMW PAHs (HQ_{NOEC} = 307 to 311) and HMW PAHs (HQ_{NOEC} = 763) exceeded NOECs for soil invertebrates (**Table 6-16**). Based on refined EPCs, concentrations of four metal COPECs exceeded soil invertebrate NOECs with HQ_{NOEC} values ranging from 1.3 (nickel and mercury) to 2.9 (zinc); refined EPCs were lower than soil invertebrate NOECs for metals. Refined risk estimates for LMW PAHs and HMW PAHs resulted in HQ_{NOEC} = 128 to 129 and HQ_{NOEC} = 318 to 463, respectively (**Table 6-16**); soil invertebrate LOECs for LMW and HMW PAHs were not identified.

For terrestrial plants, risk estimates indicate greatest exposure to cyanide and several metals. Maximum cyanide concentrations exceeded NOEC (HQ_{NOEC} = 21.4) and LOEC (HQ_{LOEC} = 6.4) values (**Table 6-16**). Maximum concentrations of several metals exceeded terrestrial plant NOECs, with HQ_{NOEC} values ranging from 1.2. (copper) to 92 (thallium); maximum metal concentrations exceeded terrestrial plant LOECs for six metals, with HQ_{LOEC} values ranging from 1.1 (zinc) to 9.2 (thallium; **Table 6-16**). Refined concentrations of nickel (HQ_{LOEC} = 1.3), thallium (HQ_{LOEC} = 3.8), and vanadium (HQ_{LOEC} = 1.4) exceeded terrestrial plant LOECs.

Figure 6-17 illustrates the spatial distribution of sampling stations within the North Percolation Pond that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. Exceedances of metal LOECs are generally concentrated in the North-East Pond near the inflow and the channel; only barium exceeded a LOEC (terrestrial plants) in the North-West Pond (**Figure 6-17**). LMW and HMW PAH exceedances of soil invertebrate NOECs follow a similar spatial pattern, with greater concentrations in the North-East Pond and channel and lower concentrations in the North-West Pond.

6.2.1.2 Aquatic Direct Contact Risk Estimate

There is a potential for adverse effects to temporary aquatic communities that may be exposed primarily to cyanide, PAHs, and metals during inundated conditions in the North Percolation Pond. Maximum cyanide concentrations in sediment exceeded the benthic invertebrate LOEC (HQ_{LOEC} = 137; **Table 6-17**). Maximum metal concentrations exceeded LOECs for benthic invertebrates, with HQ_{LOEC} values ranging from 1.2 (selenium) to 26 (nickel; **Table 6-17**). Concentrations of LMW and HMW PAHs in sediment resulted in ∑ESBTU values exceeding 1, ranging from a maximum of 72.3 based on analyses of 13 PAH compounds (∑ESBTU13) and 199 based on estimated total exposure to 34 PAHs (∑ESBTU34;

Table 6-17). Based on refined EPCs, concentrations of cyanide (HQ_{LOEC} = 41.2) and nickel (HQ_{LOEC} = 7.5) exceed the benthic invertebrate LOEC; several metal COPECs exceeded benthic invertebrate NOECs based on refined concentrations with HQ_{NOEC} values ranging from 1.4 (arsenic and copper) to 16.4 (nickel).

Direct contact exposure to cyanide, fluoride, metals, and PAHs in surface water has the potential for adverse effects to temporary aquatic receptors that may be present under inundated conditions. Maximum fluoride concentrations exceeded LOECs for benthic invertebrates (HQ_{LOEC}=5.2 to 5.5) and amphibians (HQ_{LOEC}=3.6 to 3.7). Unfiltered and filtered aluminum, cadmium, and copper concentrations exceed sample-specific LOECs (**Table 6-19**). The maximum unfiltered barium concentration exceeded the LOEC (HQ_{LOEC}=6.0; **Table 6-18**). The maximum total cyanide concentration exceeded the chronic NOEC protective of invertebrates, aquatic plants, and amphibians (**Table 6-18**). Unfiltered lead and nickel concentrations exceeded NOECs but were less than sample-specific LOECs (**Table 6-19**). Concentrations of several PAH compounds exceeded benchmarks protective of invertebrates, aquatic plants, and amphibians, resulting in HQ_{NOEC} values ranging from 1.3 to 14.8 (**Table 6-18**).

Figure 6-18 illustrates the spatial distribution of sediment sampling stations within the North Percolation Pond that exceed direct contact NOECs or LOECs for benthic invertebrates; the spatial distribution of surface water sampling stations that exceed direct contact NOECs or LOECs for aquatic receptors is presented in **Figure 6-19**. Maximum concentrations of cyanide, PAHs, and several metals were observed in sediment samples from the North-East Pond and channel. Concentrations of these COPECs are lower in the North-West Pond; however, cyanide and nickel exceed benthic invertebrate LOECs at each sampling location in the North-West Pond. Only two surface water samples were collected from the North Percolation Pond. Maximum concentrations of fluoride and most metals were observed in sample CFSWP-024 collected in the North-East Pond (**Figure 6-19**).

6.2.1.3 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to media in the North Percolation Pond Area and used maximum concentrations as the EPCs resulted in HQs exceeding 1 for every receptor except the mink (**Table 6-57**). Exposure to nickel, vanadium, cyanide, and especially PAHs, which had HQs exceeding 1,000 for some receptors, resulted in the highest HQs within this exposure area (**Appendix H**).

The refined food chain model using more realistic assumptions resulted in several constituents having an HQ greater than 1. Several metals had HQ_{LOAEL} values greater than 1 for multiple receptors, including nickel (American woodcock and short-tailed shrew), selenium (American dipper), and vanadium (American dipper). Ingestion of PAHs resulted in highly elevated HQs in the refined assumption, with LMW PAHs exceeding HQ_{NOAEL} values of 100 for the American dipper and 10 for the American woodcock, belted kingfisher, and yellow-billed cuckoo. HMW PAHs had HQ_{NOAEL} values greater than 1,000 for the American dipper, American woodcock, and short-tailed shrew, and greater than 100 for the belted kingfisher, yellow-billed cuckoo, and meadow vole. HQ_{LOAEL} values for HMW PAHs were also highly elevated, with the American dipper greater than 100 (HQ_{LOAEL}=284), and the American woodcock (HQ_{LOAEL}=103), belted kingfisher (HQ_{LOAEL}=27), yellow-billed cuckoo (HQ_{LOAEL}=29), and short-tailed shrew (HQ_{LOAEL}=23) all having HQ_{LOAEL} values greater than 10 (**Table 6-20**). Nearly all of the risk was associated with the ingestion of terrestrial and aquatic invertebrates for all constituent-receptor combinations, with 93 to 99 percent (depending on the receptor) of the total dose affiliated with this pathway.

Because the refined evaluation considers cumulative doses across multiple exposure areas for large range receptors, it is helpful to also evaluate potential risk associated with an exposure area assuming that 100 percent of exposure originates in that area in order to understand contributions from the target area itself rather than adjacent areas. For the North Percolation Pond, the dose associated with all constituents associated with elevated HQs as described in the previous paragraph originate primarily from the North Percolation Ponds Area (**Table 6-59**). Furthermore, none of these constituents were determined to be background-related in the background hypothesis testing evaluation at this exposure area (Roux, 2019). Therefore, nickel and vanadium, which had HQ_{LOAEL} values between 1 and 10 for at least one receptor, are considered to be of moderate concern for ecological receptors. Constituents with HQ_{LOAEL} values between 10 and 100 for at least one receptor, including LMW PAHs, are considered to be of high concern. Finally, HMW PAHs, which had HQ_{LOAEL} values greater than 100 for multiple receptors (American dipper and American woodcock) are considered to be of greatest concern in soil at the North Percolation Pond Area due to exposure via direct and indirect ingestion routes.

The results of the small range receptor evaluation for the North Percolation Pond Area are presented in **Figure 6-20**. Two of the eight sample locations in the former North-West Percolation Pond had concentrations that exceeded the LOAEL for short-tailed shrew based primarily on exceedances of LMW and HMW PAHs and nickel. Six of the eight locations in the North-East Percolation Pond had concentrations that exceeded the LOAEL-based benchmarks for one or both receptors. Additionally, all six sample locations in the overflow ditch connecting the two ponds had concentrations exceeding the LOAEL-based benchmark for at least one receptor, and two stations (CFSB-272 and CFSB-203) exceeded the LOAEL-based benchmark for both receptors. No sample location in this exposure area had soil concentrations that were below NOAEL-based benchmarks for both receptors.

6.2.1.4 Risk Characterization

Risk estimates for the North Percolation Pond Area indicate that the greatest potential for adverse direct contact effects is associated with exposure to cyanide, fluoride, metals, and PAHs during inundated conditions in the North-East Pond. Under inundated conditions, maximum concentrations of fluoride, aluminum, barium, cadmium, copper, and zinc in surface water exceeded LOEC benchmarks protective of aquatic communities, and 7 PAH compounds exceeded NOEC benchmarks (LOEC values were not available). In sediment, PAH ESBTUs were greater than 1 at 24 stations and greater than 10 at 13 stations. Several inorganics in sediment, including metals and cyanide, also exceeded their LOEC values. Under dry scenarios, exposure to PAHs in soil also resulted in very high exceedances of NOEC values protective of soil invertebrates. However, refined EPCs for other constituents did not exceed LOEC values. Seven metals did, however, exceed LOECs protective of plants when their maximum concentrations were considered, but the refined EPCs for only nickel, thallium, and vanadium exceeded plant-based LOECs, and all resulted in HQs below 5 (PAH impacts to plants are uncertain due to a lack of NOEC/LOEC values for these receptors).

Elevated risks associated with direct and indirect ingestion by wildlife receptors were also observed in North Percolation Pond based on the results of the food chain modeling. Several metals in soil/sediment had HQ_{LOAEL} values in the refined model greater than 1 for multiple receptors, including nickel (American woodcock and short-tailed shrew, and the yellow-billed cuckoo had an HQ_{NOAEL} that slightly exceeded 1 for this metal), selenium (American dipper), and vanadium (American dipper). Ingestion of PAHs resulted in highly elevated HQs even using the refined assumptions, with LMW PAHs exceeding HQ_{LOAEL} values of 10 for the American dipper and above 1 for the American woodcock and yellow-billed cuckoo. HQ_{LOAEL} values for HMW PAHS were even more highly elevated, with the American dipper greater than

100 (HQ_{LOAEL}=284), American woodcock (HQ_{LOAEL}=103), belted kingfisher (HQ_{LOAEL}=27), yellow-billed cuckoo (HQ_{LOAEL}=29), and short-tailed shrew (HQ_{LOAEL}=23) all having HQ_{LOAEL} values greater than 10. The ingestion of terrestrial and aquatic invertebrate prey items was the critical exposure pathway for all constituent/receptor combinations. The small range receptor evaluation indicated that every soil sampling point exceeded LOAEL-based benchmark values protective of these receptors.

The North Percolation Ponds represent low quality habitat for terrestrial or aquatic receptors, based on their use as a former wastewater management structure. Based on the degraded habitat function and value of the North Percolation Ponds, exposure pathways may be more limited than the exposure assumptions used in direct contact and ingestion pathway evaluations. However, based on the risk estimates presented in the BERA, exposure to waste related COPECs in multiple media in the North Percolation has the potential to adversely affect ecological receptors.

6.2.2 South Percolation Pond Area

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial and aquatic exposure scenarios in the South Percolation Pond Area. Given the seasonably variable hydrology of the ponds, exposure is evaluated for terrestrial receptors and aquatic receptors potentially exposed in the South Percolation Pond.

6.2.2.1 Terrestrial Direct Contact Risk Estimate

The evaluation of direct contact exposure pathways to soil indicates limited potential for adverse effects to soil invertebrate and terrestrial plant communities under dry conditions in the South Percolation Pond (**Table 6-21**). Maximum concentrations of copper (HQ_{LOEC}=1.3) and mercury (HQ_{LOEC}=2.8) exceeded LOEC values for soil invertebrates; however, refined concentrations of metals were lower than available LOECs (**Table 6-21**). Maximum concentrations of refined organic COPECs were comparable to or lower than available NOECs for soil invertebrates (**Table 6-21**).

For terrestrial plants, maximum COPEC concentrations were lower than LOECs for all COPECs, except for barium (HQ_{LOEC}=3.7) and copper (HQ_{LOEC}=1.4). Only the refined EPC for barium (HQ_{LOEC}=2.5) exceeded the LOEC for terrestrial plants.

Figure 6-21 illustrates the spatial distribution of sampling stations within the South Percolation Pond that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. Exceedances of barium, copper, mercury were isolated to station CFSB-153 near the inflow; remaining stations exceeded the terrestrial plant LOEC for barium but were below the soil invertebrate LOEC.

6.2.2.2 Aquatic Direct Contact Risk Estimate

Direct contact risk estimates for aquatic receptors potentially inhabiting the South Percolation Ponds when aquatic habitat is present indicate potential sediment exposure to metals and potential aqueous exposure to cyanide (total and free) and select metals (**Table 6-22**). Maximum concentrations of total cyanide and five metals exceeded sediment LOECs for benthic invertebrates, resulting in HQ_{LOEC} values ranging from 1.1 (nickel) to 5.0 (copper). Based on refined concentrations, total cyanide (HQ_{LOEC}=4.4), barium (HQ_{LOEC}=2.1), and copper (HQ_{LOEC}=1.4) exceeded LOECs (**Table 6-22**).

The results of AVS-SEM and pore water analyses in sediment indicate metals are not bioavailable at concentrations likely to result in adverse effects to benthic invertebrates. The maximum organic carbon normalized difference between SEM and AVS [-24.4 micromoles per gram organic carbon (µmol/g_{OC})] is less than 130 µmol/g_{OC}, indicating that divalent metals (e.g., cadmium, copper, lead, nickel, silver, and zinc) are not likely bioavailable at concentrations associated with adverse effects to benthic invertebrate receptors. Consistent with the AVS-SEM results, concentrations of divalent metals in pore water samples were below LOEC values (**Table 6-23**). Sample-specific analysis of copper concentrations in pore water indicated concentrations below sample-specific NOECs (**Table 6-24**). Maximum concentrations of barium in pore water exceeded the LOEC value (HQ_{LOEC}=10.8).

LMW and HMW PAH concentrations in sediment resulted in ∑ESBTU values less than 1 based on estimated total exposure to 34 PAHs ($∑ESBTU_{34}$; **Table 6-22**), indicating that PAH compounds are not bioavailable in sediment pore water at concentrations that would result in adverse effects to benthic invertebrate receptors. Consistent with the EqP results, the only PAHs detected in pore water were phenanthrene (5 samples) and naphthalene (1 sample). Concentrations of both compounds were below FCVs protective of benthic and aquatic receptors.

Direct contact aqueous risk estimates indicate the potential for adverse effects associated with exposure to total cyanide, aluminum (filtered and unfiltered), copper (filtered and unfiltered), and barium (**Table 6-25**). The maximum total cyanide concentration exceed the NOEC based on the criterion continuous concentration (CCC) (chronic) water quality criterion (HQ_{LOEC}=13.1 to 26.7) and the LOEC based on the criteria maximum concentration (CMC) (acute) water quality criterion (HQ_{LOEC}= 3.1 to 6.3); the refined total cyanide concentration exceeded the NOEC (HQ_{NOEC}=10.2) and LOEC (HQ_{LOEC}= 2.4). However, free cyanide concentrations were below LOECs and only slightly exceeded NOECs based on the maximum (HQ_{LOEC}= 1.9) and refined concentrations (HQ_{LOEC}= 1.1). Aluminum (unfiltered or filtered) concentrations exceeded NOECs in 6 of 26 samples, with HQ_{NOEC} values ranging from 1.2 to 37.1; aluminum (unfiltered or filtered) concentrations exceeded LOECs in 2 of 26 samples, with HQ_{LOEC} values ranging from 1.0 to 11.7 (**Table 6-26**). Copper concentrations marginally exceeded samples-specific NOECs in 1 of 17 filtered (HQ_{NOEC}=1.9) and 3 of 26 unfiltered samples (HQ_{NOEC}=1.1 to 1.5). The sample-specific LOEC was slightly exceeded in one sample in the filtered (HQ_{LOEC}=1.2) and unfiltered (HQ_{LOEC}=1.1) fractions (**Table 6-26**). Maximum and refined concentrations of barium (unfiltered and filtered) exceeded LOECs, with HQ_{LOEC} values for maximum and refined concentrations in filtered samples ranging from 13.5 to 8.0, respectively (**Table 6-25**).

Figure 6-22 illustrates the spatial distribution of sediment and pore water sampling stations within the South Percolation Pond that exceed direct contact NOECs or LOECs for benthic invertebrates; the spatial distribution of surface water sampling stations that exceed direct contact NOECs or LOECs for aquatic receptors is presented in **Figure 6-23**. Exceedances of cyanide and multiple metals, including, barium, copper, mercury, nickel, and silver were associated with station CFSB-153 near the inflow; remaining stations exceeded the LOECs, primarily for barium or cyanide in surface water or pore water (**Figure 6-22**). Surface water exceedances were generally consistent spatially within sampling events; however, exceedances were greatest during the November 2017 Supplemental South Pond Assessment sampling event.

6.2.2.3 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to media in the South Percolation Pond Area and used maximum concentrations as the EPCs resulted in HQs exceeding 1 for

multiple receptors (**Table 6-57**). Exposure to copper and BEHP resulted in the highest HQs within this exposure area (**Appendix H**).

The refined food chain model using more realistic assumptions resulted in several constituents having an HQ greater than 1. Barium was the only constituent with an HQ_{LOAEL} value greater than 1 (American dipper HQ_{LOAEL}=2.3). Cadmium, copper, vanadium, HMW PAHs, and BEHP all had HQ_{NOAEL} values greater than 1 for one or more receptors, but all were relatively low, and none had HQ_{LOAEL} values greater than 1 (**Tables 6-27 and 6-58**). Also, vanadium concentrations were determined to be comparable to background concentrations in hypothesis testing between the approximate portion of the site encompassed by the South Percolation Pond Area and background sampling area SO#2 and SO#3 (Roux, 2019). The yellow-billed cuckoo, which is evaluated using NOAEL endpoints, had HQ_{NOAEL} values that exceeded 1 for HMW PAHs (HQ = 3.9) and BEHP (HQ = 2.8).

Because the refined evaluation considers cumulative doses across multiple exposure areas for large range receptors, it is helpful to also evaluate potential risk associated with an exposure area assuming that 100 percent of exposure originates in that area in order to understand contributions from the target area itself rather than adjacent areas. For the South Percolation Pond, the dose associated with barium for the American dipper is associated primarily with the target exposure area (**Table 6-59**). The refined EPC for barium of 640 mg/kg in sediment is approximately double the soil BTV for SO#2 and SO#3 (300 mg/kg; Roux, 2019). However, because of the low HQs observed under maximum and refined assumptions, barium is considered to be of low concern from direct and indirect ingestion pathways in the South Percolation Pond Area.

The results of the small range receptor evaluation for the South Percolation Pond Area are presented in **Figure 6-24**. This exposure area contained a mixture of sample locations that were below NOAEL benchmarks for both receptors, and that exceeded NOAEL (but not LOAEL) benchmarks for the short-tailed shrew. No sample location in this exposure area had concentrations that exceeded LOAEL benchmarks for small range receptors.

6.2.2.4 Risk Characterization

During periods of inundation, exposure to cyanide and select metals in surface water has the greatest potential for adverse effects to temporary aquatic communities via direct contact exposure pathways. Based on MDEQ water quality criteria, cyanide exposure has the potential to adversely affect aquatic receptors due to concentrations exceeding chronic and acute criteria for total cyanide. However, there is a lower potential for adverse effects based on analyses of free cyanide, which is the bioavailable and potentially toxic form of cyanide and the basis for USEPA NRWQC. Concentrations of free cyanide were below the LOEC (NRWQC CMC) and only slightly exceeded the NOEC (NRWQC CCC). Aluminum concentrations were temporally variable in surface water, with maximum concentrations in unfiltered and filtered samples exceeding chronic and acute sample-specific criteria.

Potential direct contact aqueous exposure in the South Percolation Ponds is likely limited to tolerant receptors that can withstand the seasonal hydrology that controls habitat conditions. Because aquatic habitat is intermittent, the South Percolation Ponds do not likely support permanent communities of fish but may support tolerant invertebrates and seasonal use of aquatic habitat by amphibians and opportunistic species. The greatest risk via aqueous exposures to these receptors is likely associated with exposure to cyanide, aluminum, barium, and copper.

Risk estimates for COPECs in sediment during inundated conditions indicate limited potential for adverse effects to benthic invertebrates. The results of AVS-SEM and pore water analyses indicate that metals are not bioavailable at concentrations likely to result in adverse effects to benthic invertebrates. Further, $\sum ESBTU_{34}$ and direct pore water analyses indicate that PAH compounds are not bioavailable in concentrations associated with adverse effects to benthic invertebrate receptors. Exposure to cyanide in sediment is likely associated with aqueous phase concentrations in surface water and pore water. During dry periods, negligible risk is expected to terrestrial invertebrate and plant communities, as maximum and refined EPCs only marginally exceeded LOEC values for a few metals (barium, copper, and mercury).

Risk associated with direct and indirect ingestion by wildlife receptors in South Percolation Pond media is minimal based on the results of the food chain modeling. Barium in soil/sediment had an HQ_{LOAEL} value that was slightly greater than 1 for the American dipper. The refined EPC for barium of 640 mg/kg in sediment is approximately double the soil BTV for SO#2 and SO#3 of 300 mg/kg. However, because of the low HQs observed under maximum and refined assumptions, barium is of low concern from direct and indirect ingestion pathways in the South Percolation Pond Area. Furthermore, no sample location in this exposure area had concentrations that exceeded LOAEL benchmarks for small range receptors.

Although the yellow-billed cuckoo is evaluated based on NOAEL endpoints due to its current status as a federally threatened species, the likelihood of adverse effects resulting from exposure to HMW PAHs or BEHP is low. The yellow-billed cuckoo had HQ_{NOAEL} values using the spatially weighted ingestion model that exceeded 1 for HMW PAHs (3.9) and BEHP (2.8; **Table 6-58**), and exposure to these constituents was associated with the South Percolation Pond exposure area (**Table 6-59**). BEHP is a common laboratory contaminant and is unlikely to be related to site operations. HMW PAHs are associated with site operations. However, as previously discussed (see **Section 6.1.1.3**), there is a low probability of occurrence of yellow-billed cuckoo at the Site and the doses exceeding NOAEL TRVs likely overestimate risk due to the conservative estimate of dietary COPEC concentrations based on 100 percent ingestion of earthworms.

6.2.3 Cedar Creek Reservoir Overflow Ditch

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial and aquatic exposure scenarios in the Cedar Creek Reservoir Overflow Ditch. Given the seasonably variable hydrology of the ponds, exposure is evaluated for terrestrial receptors and aquatic receptors potentially exposed in the Cedar Creek Reservoir Overflow Ditch.

6.2.3.1 Terrestrial Direct Contact Risk Estimate

The evaluation of direct contact exposure pathways to soil indicates negligible potential for adverse effects to soil invertebrate and terrestrial plant communities under dry conditions in the Cedar Creek Reservoir Overflow Ditch (**Table 6-28**). Maximum concentrations of metals and HMW PAHs were below LOECs for soil invertebrates and only maximum concentrations of arsenic (HQ_{LOEC}=1.1), manganese (HQ_{LOEC}=3.6), and zinc (HQ_{LOEC}=1.1) exceeded soil invertebrate NOECs. Refined concentrations of metals were less than NOECs for all metals except manganese (HQ_{NOEC}=3.0).

For terrestrial plants, maximum concentrations of metals and di-n-butyl phthalate were below LOECs, except for slight exceedances of maximum concentrations of barium (HQ_{LOEC}=1.1) and manganese (HQ_{LOEC}=1.5). Refined concentrations of barium (HQ_{LOEC}=1.1) and manganese (HQ_{LOEC}=1.2) also slightly exceeded terrestrial plant LOECs (**Table 6-28**).

Figure 6-25 illustrates the spatial distribution of sampling stations within the Cedar Creek Reservoir Overflow Ditch that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. Exceedances of LOECs were limited to barium and manganese. Manganese concentrations are generally consistent from upgradient (CFSDP-013) to downgradient stations, indicating that concentrations of manganese in the Cedar Creek Reservoir Overflow Ditch may be related to regional soil conditions and not site-related operations and pathways; concentrations of barium were also consistent from the most upgradient to downgradient sample, indicating limited site-related influence (**Figure 6-25**). Further, maximum concentrations of manganese (1,640 mg/kg) and barium (295 mg/kg) in the Cedar Creek Reservoir Overflow Ditch were comparable to or lower than BTV values calculated for the Revett Formation background soil type (SO#4) (1,566 mg/kg and 734 mg/kg for manganese and barium, respectively) that was sampled to reflect soil conditions near the base of Teakettle Mountain (Roux, 2019). These findings indicate that direct contact exposure to barium and manganese do not represent a substantial incremental risk above background risk.

6.2.3.2 Aquatic Direct Contact Risk Estimate

Direct contact risk estimates for aquatic receptors potentially inhabiting the Cedar Creek Overflow Ditch when aquatic habitat is present indicate limited potential for adverse effects for benthic invertebrates exposed to metals and PAHs in sediment, and aqueous exposure to free cyanide and select metals. Maximum concentrations of cyanide (HQ_{LOEC}=1.5) and manganese (HQ_{LOEC}=1.5) only slightly exceeded LOECs for benthic invertebrates; only the refined manganese concentration exceeded the LOEC (HQ_{LOEC}=1.2; **Table 6-29**). For PAHs, ∑ESBTU values were less than 1.0 for all stations except CFSB-284 ($\sum ESBTU_{13}$ = 7.7; $\sum ESBTU_{34}$ = 21.2). Elevated ∑ESBTU values at this station were attributed to low organic carbon concentrations (0.006 percent) and relatively low total PAH concentrations (7.4 mg tPAH/kg).

Direct contact aqueous risk estimates indicate negligible potential for adverse effects associated with exposure to free cyanide and select metals (**Table 6-30**). The maximum free cyanide concentration was comparable to the NOEC for aquatic receptors (HQ_{NOEC}=1.1) but was lower than the LOEC. Unfiltered aluminum concentrations exceeded sample-specific NOECs in 2 of 27 samples, with HQ_{NOEC} values ranging from 1.9 to 10.3. Unfiltered aluminum concentrations exceeded sample-specific LOECs in 1 of 27 samples (HQ_{LOEC}=6.5; **Table 6-31**). Filtered aluminum concentrations were below NOECs. Maximum and refined concentrations of barium (unfiltered and filtered) exceeded LOECs, with HQ_{LOEC} values for maximum and refined concentrations in filtered samples ranging from 5.4 to 5.6 and 2.6 to 2.7, respectively (**Table 6-30**). The maximum concentration of manganese slightly exceeded the LOEC (HQ_{LOEC}=1.6), but the refined concentration was less than the NOEC and LOEC (**Table 6-30**).

Figure 6-26 illustrates the spatial distribution of sediment and pore water sampling stations within the Cedar Creek Reservoir Overflow Ditch that exceed direct contact NOECs or LOECs for benthic invertebrates; the spatial distribution of surface water sampling stations that exceed direct contact NOECs or LOECs for aquatic receptors is presented in **Figure 6-27**. Sediment exceedances of manganese were identified at four stations; however, as stated in the previous section, manganese concentrations in the Cedar Creek Reservoir Overflow Ditch are consistent upgradient to downgradient within the ditch

and also to concentrations observed in the SO#4 background dataset. The only PAH exceedance observed at CFSB-284 was attributed to low organic carbon concentrations (0.006 percent) and relatively low total PAH concentrations (7.4 mg tPAH/kg). Barium concentrations in surface water samples were consistent upgradient to downgradient and during the June 2018 sampling event. The maximum barium concentration was observed at downgradient station (CFSWP-039) during the October 2018 sampling event; however, there are no other stations for comparison during that sampling event. These findings indicate that direct contact exposure within the Cedar Creek Reservoir Overflow Ditch are consistent with regional conditions and not associated with site-related pathways.

6.2.3.3 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to media in the Cedar Creek Reservoir Overflow Ditch Area and used maximum concentrations as the EPCs resulted in HQs for arsenic, nickel, selenium, vanadium, zinc, and HMW PAHs exceeding 1 for three different receptors (**Table 6-57**). However, all HQs were below 5 (**Appendix H**).

The refined food chain model using more realistic assumptions resulted in several constituents having an HQ greater than 1, but only copper (American woodcock and yellow-billed cuckoo), Aroclor 1254 (American woodcock and yellow-billed cuckoo), and HMW PAHs (yellow-billed cuckoo) had HQ_{LOAEL} values that exceeded 1 (**Table 6-32**). All HQ_{LOAEL} values were less than 5. The yellow-billed cuckoo, which is evaluated using NOAEL endpoints, also had HQ_{NOAEL} values that slightly exceeded 1 for LMW PAHs, BEHP, and dioxins/furans.

Because the refined evaluation considers cumulative doses across multiple exposure areas for large range receptors, it is helpful to also evaluate potential risk associated with an exposure area assuming that 100 percent of exposure originates in that area in order to understand contributions from the target area itself rather than adjacent areas. For the Cedar Creek Reservoir Overflow Ditch Area, none of the constituents resulting in elevated HQs were directly related to this exposure area. Because the area being assessed is a thin, linear polygon, it is strongly influenced by adjacent exposure areas for the cumulative risk calculated for most receptors. When only exposure to the Cedar Creek Overflow Ditch exposure is considered, only HQ_{NOAEL} values for barium (American dipper = 1.8), nickel (short-tailed shrew = 2), vanadium (American dipper = 1.9), and HMW PAHs (American dipper = 2.3) slightly exceeded 1; all HQ_{LOAEL} values were below 1 (**Table 6-59**). Therefore, constituents in media associated with the Cedar Creek Reservoir Overflow Ditch Area are considered to be of low concern for ecological receptors.

The results of the small range receptor evaluation for the Cedar Creek Reservoir Overflow Ditch Area are presented in **Figure 6-28**. Seven of the eight soil sample locations along this exposure area had concentrations that exceeded the NOAEL (but not the LOAEL) for the shrew. The most downstream location in the ditch (CFSDP-009) did not have any exceedances of NOAEL benchmarks for either receptor.

6.2.3.4 Risk Characterization

During periods of inundation, direct contact risk associated with surface water and sediment is expected to be minimal. Some exceedances of NOEC and LOEC in both media were noted, but consideration of BTVs, concentration gradients, the low magnitude and frequency of exceedances, and other factors suggest that site-related toxicity related to these constituents is unlikely. For times of the year when inundation does not occur, direct contact risk to terrestrial organisms is expected to be negligible

relative to background risk. No constituents had maximum concentrations that exceeded their LOECs for terrestrial invertebrates and plants, except for barium and manganese, which both had slight exceedances of LOECs protective of invertebrates. Refined risk estimates indicate minor exceedances of manganese NOECs for soil invertebrates and barium and manganese NOECs for terrestrial plants. However, maximum concentrations of manganese and barium approximate or are lower than their respective BTVs for the SO#4 reference area that was sampled to reflect soil conditions near the base of Teakettle Mountain (Roux, 2019).

The food chain modeling results for the Cedar Creek Reservoir Overflow Ditch resulted in HQ_{LOAEL} values that exceeded 1 for copper (American woodcock and yellow-billed cuckoo), Aroclor 1254 (American woodcock and yellow-billed cuckoo), and HMW PAHs (yellow-billed cuckoo). However, all HQ_{LOAEL} values were less than 5, and further evaluation indicated that adjacent exposure areas were responsible for nearly all of the doses resulting in these exceedances. The small-range receptor evaluation revealed that a single sample in this exposure area had concentrations that exceeded only the NOAEL benchmark, but no benchmarks based on LOAELs were exceeded in this exposure area. Therefore, no constituents in media associated with the Cedar Creek Reservoir Overflow Ditch Area are considered to be of concern for direct or indirect ingestion by wildlife receptors.

6.2.4 Northern Surface Water Feature

The following sections present the direct contact and ingestion risk estimates and the baseline ecological risk characterization for terrestrial and aquatic exposure scenarios in the Northern Surface Water Feature.

6.2.4.1 Terrestrial Direct Contact Risk Estimate

Risk estimates and risk characterization for direct contact exposure pathways are presented below for the Northern Surface Water Feature. The evaluation of direct contact exposure pathways to soil indicates negligible potential for adverse effects to soil invertebrate and terrestrial plant communities under dry conditions in the Northern Surface Water Feature (**Table 6-33**). Refined risk estimates slightly exceeded NOECs for soil invertebrates for arsenic, barium, and manganese (HQ = 1.8) and terrestrial plant NOECs for barium, manganese, and selenium (HQ = 2.2 to 5.3). Maximum concentrations of metals were below LOECs for soil invertebrates, with only limited exceedances of soil invertebrate NOECs (HQ_{NOEC}=1.1 to 2.7). For terrestrial plants, maximum concentrations of barium (HQ_{LOEC}=3.5) and selenium (HQ_{LOEC}=1.5) were the only COPECs to exceed LOECs for terrestrial plants; the refined barium concentration was the only COPEC to exceed the LOEC (HQ_{LOEC}=2.3; **Table 6-33**).

Figure 6-29 illustrates the spatial distribution of sampling stations within the Northern Surface Water Feature that exceed direct contact NOECs or LOECs for soil invertebrate or terrestrial plant communities. Barium concentrations exceeded the terrestrial plant LOEC at all but two stations within the Northern Surface water Feature; observed barium concentrations were 1- to 3-times the BTV (300 mg/kg) calculated for the background soil area SO#1 (**Figure 6-29**).

6.2.4.2 Aquatic Direct Contact Risk Estimate

Direct contact risk estimates for aquatic receptors potentially inhabiting the Northern Surface Water Feature when aquatic habitat is present indicate limited potential for adverse effects for benthic

invertebrates exposed to metals in sediment and aqueous exposure to select metals. Maximum concentrations of barium (HQ_{LOEC}=3.0) and selenium (HQ_{LOEC}=1.5) were the only COPECs to exceed LOECs for benthic invertebrates; only the refined barium concentration exceeded the LOEC (HQ_{LOEC}=2.0; **Table 6-34**). For PAHs sediment, ∑ESBTU values were less than 1.0 for all stations, indicating negligible potential for adverse effects to benthic invertebrates exposed to PAHs in sediment. Sediment pore water samples collected at Northern Surface Water Feature stations indicate that barium is the only COPEC to exceed LOECs for aquatic receptors (**Table 6-35; Table 6-36**).

Direct contact aqueous risk estimates indicate limited potential for adverse effects associated with exposure to unfiltered aluminum and unfiltered and filtered barium (**Table 6-37**). Unfiltered aluminum concentrations exceeded sample-specific NOECs in 3 of 16 samples, with HQ_{NOEC} values ranging from 1.2 to 3.8. unfiltered aluminum concentrations exceeded sample-specific LOECs in 2 of 16 samples (HQ_{LOEC}=1.2 and 1.9; **Table 6-38**). Filtered aluminum concentrations were below NOECs. Maximum and refined concentrations of barium (unfiltered and filtered) exceeded LOECs, with HQ_{LOEC} values for maximum and refined concentrations in filtered samples ranging from 5.9 to 3.8, respectively (**Table 6-37**).

Figure 6-30 illustrates the spatial distribution of sediment and pore water sampling stations within the Northern Surface Water Feature that exceed direct contact NOECs or LOECs for benthic invertebrates. The spatial distribution of surface water sampling stations that exceed direct contact NOECs or LOECs for aquatic receptors is presented in **Figure 6-31**. LOECs exceedances in sediment/pore water are primarily associated with barium concentrations in pore water, which were greatest near the western edge of the feature (CFSDP-049). Surface water barium concentrations were generally consistent throughout the Northern Surface Water Feature, but similar to pore water, the greatest concentration was observed near station CFSDP-049. Except for stations near the western edge of the feature, barium concentrations in pore water and surface water are not substantially greater than the BTV calculated from upgradient filtered samples off-site in Cedar Creek (99.8 µg/L). These findings indicate that direct contact exposure to barium in pore water and surface water in the Northern Surface Water Feature does not represent a substantial incremental risk above background risk upstream of the Site in Cedar Creek.

6.2.4.3 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to media in the Northern Surface Water Feature Area and used maximum concentrations as the EPCs resulted in HQs exceeding 1 for barium, copper, selenium, and vanadium for several receptors (**Table 6-57**). Exposure to barium and selenium resulted in the highest HQs within this exposure area (**Appendix H**).

The refined food chain model using more realistic assumptions resulted in several metals having an HQ greater than 1, but only barium and selenium for the American dipper had HQ_{LOAEL} values that marginally exceeded 1 (**Tables 6-39 and 6-58**). The HQ_{LOAEL} values for both metals were less than 5. The critical pathway for these two metals was ingestion of invertebrates, which accounted for 99 percent of the dose of both barium and selenium. The results of the background hypothesis testing indicate that both metals were elevated relative to background soil concentrations in this area (Roux, 2019). However, the refined EPCs for barium (586 mg/kg) and selenium (1.62 mg/kg) in soil/sediment were not highly elevated compared to the BTVs in soil for these constituents in SO#1 (300 mg/kg and 1.4 mg/kg, respectively; Roux, 2019).

Because the refined evaluation considers cumulative doses across multiple exposure areas for large range receptors, it is helpful to also evaluate potential risk associated with an exposure area assuming that 100 percent of exposure originates in that area in order to understand contributions from the target area itself rather than adjacent areas. For the Northern Surface Water Feature, the dose associated with barium and selenium are associated primarily with the target exposure area (**Table 6-59**). However, because of the low HQs observed under maximum and refined assumptions, barium and selenium in Northern Surface Water Feature are considered to be of low concern due to direct and indirect ingestion pathways in this exposure area.

The results of the small range receptor evaluation for the Northern Surface Water Feature Area are presented in **Figure 6-32**. All eight of the soil sample locations in the southwestern portion of the site were below NOAEL benchmarks for both small range receptors. The two sample locations in the northeastern portion of this exposure area (CFSDP-046 and CFSDP-047) exceeded NOAEL-based soil benchmarks for selenium.

6.2.4.4 Risk Characterization

During periods of inundation, toxicity associated with direct contact with surface water and sediment is expected to be limited relative to background exposure. Refined risk estimates indicated surface water exceedances of NOECs for aluminum, barium, and iron. Maximum surface water concentrations of aluminum and barium exceeded LOECs; however, only barium had filtered refined concentrations that exceeded LOECs. The refined EPC for barium in surface water also exceeded its LOEC. Refined sediment risk estimates for total cyanide, barium, and selenium exceeded sediment NOECs; barium was also the only constituent with a refined EPC that exceeded its sediment LOEC protective of benthic invertebrates (HQ_{LOEC} = 2). However, barium exposure in the Northern Surface Water Feature is not substantially greater than background exposure upstream of the Site in Cedar Creek.

Potential direct contact aqueous exposure during periods of inundation in the Northern Surface Water Feature is likely limited to tolerant receptors that can withstand the seasonal hydrology that controls habitat conditions. Further, inundation in the Northern Surface Water Feature varies interannually. The feature was inundated when it was identified during a field visit in May 2016; however, the feature was dry during a field visit in May 2019. Because aquatic habitat is seasonal and varies interannually, the Northern Surface Water Feature does not support permanent communities of benthic invertebrates or fish, but may support temporary communities of tolerant invertebrates and seasonal use of aquatic habitat by amphibians and opportunistic species.

During dry periods, negligible risk is expected for soil invertebrates, as the maximum EPCs for all constituents were below LOECs protective of these organisms. Barium slightly exceeded its LOEC for the protection of terrestrial plants, but this exceedance was below 5.

For the wildlife ingestion model, only barium and selenium had HQ_{LOAEL} values that were greater than 1 (American dipper), but values for both of these metals were less than 5, and refined EPCs were not highly elevated compared to relevant BTVs. Ingestion of invertebrate prey items was the critical pathway for both metals. It should be noted that the higher HQs for the American dipper compared to other receptors was the result of the American dipper hypothetically ingesting benthic invertebrates that have body burdens modeled on uptake from sediment, rather than terrestrial invertebrates that have body burdens modeled on uptake from soil. The uptake factors for sediment to benthic invertebrates used in the food chain model resulted in estimated benthic invertebrate prey item

concentrations that were 30-times and 5-times higher for barium and selenium, respectively, than for terrestrial invertebrate prey items that were assumed to be exposed to these metals in soil (**Appendix E**). The Northern Surface Water Feature is an intermittently wet area, and therefore would not support a permanent benthic invertebrate community. Therefore, risks associated with the American dipper are likely overestimated. The small-range receptor evaluation indicated that all samples were below LOAEL-based benchmarks.

Because of the low HQs observed under maximum and refined assumptions, barium and selenium risks associated with direct and indirect ingestion pathways in the Northern Surface Water Feature are considered to be of low concern in this exposure area.

6.3 Aquatic Exposure Areas

The following sections present risk estimates and risk characterizations for aquatic exposure areas evaluated at the Site.

6.3.1 Flathead River

Risk estimates and the baseline risk characterization for direct contact and ingestion exposure pathways are presented below for the Flathead River. Risk estimates are presented based on sediment and surface water data for the entire Flathead River dataset including the Backwater Seep Sampling Area that has been regulated under MPDES Permit No. MT0030066 and for Flathead River data excluding samples within the Backwater Seep Sampling Area (**Figure 2-2**).

6.3.1.1 Direct Contact Risk Estimate

Risk estimates and risk characterization for direct contact exposure pathways are presented below for the Flathead River. Risk estimates are presented based on sediment and surface water data for the entire Flathead River dataset including the Backwater Seep Sampling Area and for the Flathead River data excluding samples within the Backwater Seep Sampling Area.

Direct contact risk estimates indicate that the greatest exposure to COPECs in sediment, pore water, and surface water within the Flathead River is associated with the Backwater Seep Sampling Area. Benthic invertebrate risk estimates indicate that maximum COPEC concentrations exceed benthic invertebrate NOECs in sediment for total cyanide and $\sum ESBTU_{34}$ values (**Table 6-40; Figure 6-33**). Maximum COPEC concentrations in sediment are below benthic invertebrate LOECs for all COPECs, except total cyanide and $\sum ESBTU_{34}$ values for PAHs at three stations (**Table 6-40; Figure 6-33**). Based on refined sediment exposure concentrations, only cyanide exceeded the benthic invertebrate LOEC (HQ_{LOEC}=1.7; **Table 6-40**).

Pore water samples indicate exceedances of benthic invertebrate NOECs for free cyanide, fluoride, and barium and LOECs for barium and free cyanide. Maximum concentrations of free cyanide exceed pore water NOECs (HQ_{NOEC}=12.0) and LOECs (HQ_{LOEC}=2.8; **Table 6-41**). Maximum barium concentrations exceed NOECs and LOECs (HQ_{LOEC}=6.7); however, barium concentrations in pore water remain consistent in samples collected upstream of the site on the Flathead River (CFPWP-017) to barium concentrations in samples collected within the Backwater Seep Sampling Area (**Figure 6-33**), and barium concentrations outside of the Backwater Seep Sampling Area are consistent with background (Roux, 2019). This

indicates that barium concentrations in pore water may be associated with regional conditions and not related to pathways from the site. The results of AVS-SEM and pore water analyses in sediment indicate divalent metals are not bioavailable at concentrations likely to result in adverse effects to benthic invertebrates (less than 130 $\mu mol/g_{OC}$).

The greatest direct contact exposure to surface water in the Flathead River is also associated with samples collected in the Backwater Seep Sampling Area. Based on the entire Flathead River dataset, maximum concentrations of cyanide (total and free), unfiltered aluminum, barium (filtered and unfiltered), and iron exceeded NOECs based on chronic NRWQC and DEQ-7 criteria for the protection of aquatic life (**Table 6-42**). Maximum concentrations of cyanide (total and free), unfiltered aluminum, and barium (filtered and unfiltered) exceeded LOECs based on acute criteria for the protection of aquatic life (**Table 6-42**). Maximum total and free cyanide concentrations exceeded NOECs (total cyanide HQ_{NOEC}= 63.1 to 72.7; free cyanide HQ_{NOEC}=8.1 to 26.7) and LOECs (total cyanide HQ_{NOEC}=14.9 to 17.2; free cyanide HQ_{LOEC}=1.9 to 6.3; **Table 6-42**). Unfiltered aluminum concentrations exceeded sample-specific NOECs in 21 of 76 samples, with HQ_{NOEC} values ranging from 1.0 to 28.5 (**Table 6-43**). Unfiltered aluminum concentrations exceeded sample-specific LOECs in 8 of 76 samples (HQ_{LOEC}=1.6 to 17.7; **Table 6-43**). Filtered aluminum concentrations were below NOECs. Maximum barium concentrations exceeded NOECs (filtered HQ_{NOEC}=49.0; unfiltered HQ_{NOEC} 55.4) and LOECs (filtered HQ_{LOEC}=4.9; unfiltered HQ_{LOEC} 5.5; **Table 6-42**).

Refined exposure estimates for cyanide (total and free) and barium (filtered and unfiltered) based on the entire Flathead River dataset also exceeded chronic NOECs and acute LOECs. Refined total and free cyanide concentrations exceed NOECs (total cyanide HQ_{NOEC}=11.9 to 35.2; free cyanide HQ_{NOEC}=4.5 to 5.2) and LOECs (total cyanide HQ_{LOEC}=2.8 to 8.3; free cyanide HQ_{LOEC}=1.1 to 1.2; **Table 6-42**). Refined barium concentrations exceeded NOECs (filtered HQ_{NOEC}=26.6; unfiltered HQ_{NOEC}=30.0) and LOECs (filtered HQ_{LOEC}=2.7; unfiltered HQ_{LOEC}=3.0).

Excluding samples from the Backwater Seep Sampling Area, maximum sediment concentrations only exceeded NOECs and LOECs for PAHs; all other COPECs were less than NOECs (**Table 6-44**). For PAHs, $\sum$ESBTU values exceeded 1.0 for station CFSDP-036 ($\sum ESBTU_{13}$ = 9.8; $\sum ESBTU_{34}$ = 27). Elevated $\sum$ESBTU values at this station were attributed to low organic carbon concentrations (0.01 percent) and relatively low total PAH concentrations (1.35 mg tPAH/kg). Pore water samples indicate exceedances of benthic invertebrate LOECs for barium (**Table 6-45)**; however, as previously stated, barium concentrations in pore water remain consistent in samples collected upstream of the site to downstream of the site (**Figure 6-33**), indicating that barium concentrations in pore water may be associated with regional conditions and not related to pathways from the site.

Excluding surface water data from the Backwater Seep Sampling Area, maximum concentrations of barium and unfiltered aluminum exceeded NOECs and LOECs for aquatic organisms (**Table 6-46**). Outside of stations within the Backwater Seep Sampling Area and stations along the shoreline immediately downstream of the Backwater Seep Sampling Area (CFSWP-26 through CFSWP-28), free and total cyanide concentrations were below NOEC benchmarks based on NRWQC CCC and MDEQ chronic criteria, respectively. Unfiltered aluminum concentrations exceeded sample-specific NOECs in 3 of 40 samples, with HQ_{NOEC} values ranging from 1.0 to 28.5. Unfiltered aluminum concentrations exceeded sample-specific LOECs in 3 of 40 samples (HQ_{LOEC}=3.5 to 17.7; **Table 6-47**). Filtered aluminum concentrations were below NOECs. Maximum and refined concentrations of barium (unfiltered and filtered) exceeded NOECs and LOECs, with HQ_{LOEC} values for maximum and refined concentrations in filtered samples ranging from 3.6 to 2.1, respectively (**Table 6-46**). However, similar to pore water,

barium concentrations in surface water remain consistent in samples collected the main river channel upstream of the site (CFSWP-017) to downstream of the site (CFSWP-001; **Figure 6-34**). Further, barium concentrations in the Flathead River outside of the Backwater Seep Sampling Area are generally lower than the BTVs calculated for upgradient filtered (122 µg/L) and unfiltered (130 µg/L) datasets. These findings indicate that barium concentrations in surface water is likely associated with regional conditions and not related to pathways from the site.

6.3.1.2 Ingestion Risk Estimate

The screening-level food ingestion model that assumed 100 percent exposure to surface water and sediment in the Flathead River and used maximum concentrations as the EPCs resulted in HQs exceeding 1 for aluminum, vanadium, cyanide, and HMW PAHs for one or more of the aquatic receptors (**Table 6-57**). However, all HQ values were below 10 and no HQ_{LOAEL} values exceeded 1 based on maximum EPCs (**Appendix H**).

The screening-level exposure scenario for wildlife in the Flathead River modeled the maximum exposure scenario for the potential ingestion of total cyanide through dietary, drinking water, and incidental ingestion pathways based on maximum EPCs for surface water (378 µg/L) and sediment (8.3 mg/kg) measured in samples collected from the Backwater Seep Sampling Area (CFSWP-004 and CFSWP-003 for surface water and sediment, respectively). In addition to maximum EPCs, the screening-level wildlife ingestion model assumes an AUF of 1 and therefore, represents the maximum exposure scenario for wildlife that may be associated with a single-dose exposure to total cyanide via ingestion pathways while foraging within the Backwater Seep Sampling Area. As presented in **Appendix H1**, estimated maximum daily doses of total cyanide were calculated for American dipper (Table H12-2), belted kingfisher (Table H12-3), and mink (Table H12-4) and compared to chronic TRVs for cyanide. This maximum exposure scenario for cyanide resulted in a chronic HQ_{NOAEL} values greater than 1 for American dipper (HQ_{NOAEL} = 2.3) and belted kingfisher (HQ_{NOAEL} = 1.5); maximum estimated doses for these avian receptors were less than the chronic LOAEL TRV. The drinking water ingestion pathway accounted for 69 percent of the total dose modeled for American dipper and the entire total cyanide dose modeled for belted kingfisher. The maximum modeled mink exposure for total cyanide resulted in a chronic HQ_{NOAEL} value less than 1.

The screening-level risk estimates based on maximum exposure and chronic TRVs for total cyanide are protective of acute exposure scenarios for wildlife that may occur during single-dose exposure while foraging within the Backwater Seep Sampling Area. The chronic mammalian TRVs for cyanide were based on chronic endpoints (LANL, 2017); therefore, acute mammalian TRVs would be greater than the chronic TRVs evaluated in the model. Chronic avian TRVs for total cyanide were based on a lethal dose to 50 percent of test organisms (LD_{50}) endpoint derived from a single-dose acute study (Wiemeyer et al., 1986, as cited in LANL, 2017). The chronic avian NOAEL was derived by dividing the LD_{50} by an uncertainty factor of 100 (LANL, 2017); the chronic LOAEL was estimated by multiplying the chronic NOAEL by an uncertainty factor of 10 (LANL, 2017). Comparing the doses estimated in **Appendix H1** based on the maximum detected total cyanide EPCs in the Backwater Seep Sampling Area directly to the acute LD_{50} results in a maximum HQ_{LD50} of 0.02 for modeled avian receptors. Thus, acute wildlife risks associated with a single-dose exposure scenario of ingesting the maximum detected concentration of cyanide in surface water within the Backwater Seep Sampling Area 100 percent of the time indicates minimal acute risk for modeled wildlife receptors.

The refined food chain model using more realistic assumptions resulted in only vanadium (American dipper and belted kingfisher) and HMW PAHs (American dipper, belted kingfisher, and mink) having an HQ_{NOAEL} greater than 1 (**Table 6-48**). No HQ_{LOAEL} values exceeded 1. Risk associated to vanadium and HMW PAHs originated from sediment (rather than surface water) (**Appendix H2**). Vanadium and several PAHs were found to be higher than upgradient reference area sediment data in the hypothesis testing (Roux, 2019). However, because of the very low HQs in the refined evaluation (all HQ_{NOAEL} values were below 5, no HQ_{LOAEL} values above 1) (**Table 6-59**), ecological risk to wildlife associated with direct and indirect ingestion of media in the Flathead River is considered minimal.

6.3.1.3 Risk Characterization

The evaluation of Flathead River sediment, pore water, and surface water data indicate that the greatest potential for ecological exposure to site-related constituents is associated with aqueous exposure pathways within the Backwater Seep Sampling Area, and areas where groundwater containing cyanide and fluoride discharges to surface water. Elevated sodium concentrations in surface water samples from the Backwater Seep Sampling Area are consistent with elevated sodium concentrations observed in groundwater wells adjacent to the Backwater Seep Sampling Area that are screened within the upper hydrogeologic unit. Elevated sodium concentrations in these wells are indicative of the potential groundwater discharge pathway (Roux, 2019). The discharge of cyanide and fluoride in groundwater to the Flathead River adjacent to the Site was previously authorized by MPDES permit number MT-0030066 since first issued in May 1994, and subsequently renewed in 1999 and July 2014. On January 24, 2019, MDEQ provided a Notice of Intent to terminate the permit.

Surface water exposure was greatest to cyanide (total and free), barium, and aluminum, with greater concentrations observed in the Backwater Seep Sampling Area and adjacent stations immediately downstream of the Backwater Seep Sampling Area (CFSWP-26 through CFSWP-28). Attenuation of surface water concentrations occurs rapidly with increasing distance from the Backwater Seep Sampling Area, particularly during periods of elevated discharge within the Flathead River (**Figure 6-34; Figure 6-35**). Outside of the stations within the Backwater Seep Sampling Area and stations along the shoreline immediately downstream of the Backwater Seep Sampling Area (CFSWP-26 through CFSWP-28), free and total cyanide concentrations did not exceed chronic NRWQC- and DEQ-7-based benchmarks, respectively, in multiple rounds of surface water sampling events. At surface water sampling stations on the shoreline immediately downstream of the Backwater Seep Sampling Area (CFSWP-26 through CFSWP-28), total cyanide exceeded the chronic DEQ-7-based NOEC and acute DEQ-7-based LOEC in at least one sample at each station. Free cyanide concentrations were below the NRWQC-based NOEC at stations CFSWP-26 and CFSWP-27, but exceeded the free cyanide NOEC at CFSWP-28. None of the stations on the shoreline immediately downstream of the Backwater Seep Sampling Area (CFSWP-26 through CFSWP-28) exceeded the acute NRWQC-based LOEC for free cyanide. This finding indicates that the potential area of exposure to aquatic receptors at concentrations exceeding NOECs and LOECs based on NRWQC (free cyanide) and MDEQ (total cyanide) benchmarks is spatially-limited to a groundwater-surface water mixing zone along the shoreline within and immediately adjacent to the Backwater Seep Sampling Area.

A statistical evaluation of spatial and temporal trends was conducted to assess the effect of discharge percentile on COPEC concentrations in the Backwater Seep Sampling Area and adjacent stations in the Flathead River. Variability in surface water concentrations of fluoride, total cyanide, aluminum, and barium across sampling phases were grouped by three areas: 1) the Downstream Portion of the Flathead River – stations CFSWP-001, -034, -002, -035, -026, -027, and -028; 2) the Backwater Seep

Sampling Area of the Flathead River – stations CFSWP-003, -004, and -005); and, 3) the Flathead Riparian Area Channel (CFSWP-029 to -033) (**Figure 4-13**). The effect of discharge percentiles discussed in **Section 4.1.2** on surface water concentrations of fluoride and total cyanide as well as unfiltered and filtered aluminum and barium were evaluated for each area using a one-way analysis of variance (ANOVA). Constituent concentrations are illustrated in **Figure 6-35** by discharge percentile. In addition, the suspected interaction effects of discharge percentiles and area on concentration were evaluated to assess whether the temporal response in concentration was consistent for each area (**Figure 6-36**). The results of one- and two-way ANOVAs are summarized in **Table 6-60**.

Findings from the evaluation of the effect of discharge percentile on concentration for each area supports the observations discussed in the ECSM (**Section 3.3.5**). Significantly less fluoride was observed in the Downstream Portion of the Flathead River and the Backwater Seep Sampling Area at greater discharge percentiles (**Table 6-60**). Discharge percentile did not have a significant effect on fluoride concentration in the Flathead Riparian Area Channel. Cyanide exhibited similar patterns as fluoride in the Downstream Portion of the Flathead River and Backwater Seep Sampling Area. However, significantly greater cyanide was observed in the Flathead Riparian Area Channel at periods of elevated discharge (**Table 6-60**). Significant two-way interactions of area and discharge (Q) percentile indicate that the riparian channel does not respond in a consistent manner to the Backwater Seep Sampling Area and downstream portion of the Flathead River (**Table 6-60; Figure 6-36**). Discharge percentiles did not have a significant effect on filtered or unfiltered aluminum concentrations across all three areas. Patterns of unfiltered and filtered barium were consistent across the Downstream Portion and Backwater Seep Sampling Area, with significantly lower concentrations during elevated flow conditions (**Table 6-60**). Concentrations of barium outside of the Backwater Seep Sampling Area were also consistent with concentrations detected in the main channel of the Flathead River, as well as the background area in the Flathead River upstream of the Site.

The potential for adverse ecological effects associated with COPEC concentrations in the Backwater Seep Sampling Area was further evaluated based on biological data collected by CFAC in support of the MPDES permit for Outfall 006. CFAC has conducted 18 quarterly Whole Effluent Toxicity (WET) testing studies (Fourth Quarter 2014 to First Quarter 2019) to evaluate the potential for acute toxic effects in the Backwater Seep Sampling Area. Toxicity tests were conducted using Fathead Minnow (*Pimephales promelas*) and the daphnid (*Ceriodaphnia dubia*) and a dilution series of groundwater seep water from Outfall 006 (USEPA, 2002). Fathead minnow is a relatively sensitive fish species to cyanide exposure (Broderius et al., 1977; Doudoroff, 1956; Smith et al., 1978) and daphnids are more sensitive to cyanide exposure than aquatic insects and other macroinvertebrate test organisms (Gensemer et al., 2007; Gensemer et al., 2006).

Exposure to 100 percent effluent from the groundwater seep did not result in an LC_{50} for Flathead Minnow or daphnid test organisms in any sample (**Table 6-61**). These results indicate that cyanide or other COPECs are not likely present in a toxic form or at concentrations in surface water in the Backwater Seep Sampling Area that are sufficiently elevated to elicit acute toxicity in invertebrate or fish test organisms that are relatively sensitive to cyanide exposure.

Further analysis of the results of 18 quarterly WET testing samples indicates that aqueous exposure to the groundwater seep dilution series did not materially affect the survival of Fathead Minnow and had a relatively minor effect on the survival of daphnid test organisms in short-term exposures (48- to 96-hours; **Figure 6-37**). A one-way ANOVA was conducted to test for statistically significant differences ($p < 0.05$) in mean percent survival across the dilutions series for Fathead Minnow and daphnid test

organisms assessed in 18 quarterly sampling events. There was no significant effect of the percent effluent on the percent survival of Fathead Minnow in undiluted effluent (100 percent effluent) or the dilution series exposures ($p > 0.05$; **Figure 6-37; Table 6-62**). However, a statistically significant ($p < 0.001$) main effect of percent effluent was identified for the percent survival of daphnid test organisms. Further pairwise testing of the effect of percent effluent using Tukey's Honest Significant Difference (HSD) test indicated significant differences ($p < 0.05$) in mean percent survival in undiluted effluent (100 percent effluent) compared to the dilution series (50 - 6.25 percent effluent) and the 0 percent effluent control treatment (**Figure 6-37; Table 6-62**). However, the difference in mean survival was relatively minor, as mean survival (± standard error) of daphnid test organisms in the undiluted treatment (100 percent effluent) was 91.4 ± 1.9 percent. Mean daphnid survival in the diluted treatments (50 - 6.25 percent effluent) was not significantly different from mean survival in the control sample (0 percent effluent) or any diluted exposures (**Figure 6-37; Table 6-62**). These findings indicate that 50 percent or greater dilution of discharging groundwater by surface water from the Flathead River in the Backwater Seep Sampling Area is likely sufficient to mitigate any short-term effects on the survival of representative fish and invertebrates.

The lack of substantial mortality relative to control across the WET testing dilution series also indicates that no other COPECs were present in test samples in a form or concentrations that are acutely toxic to aquatic life during short-term exposures. Further, the lack of substantial mortality in the dilution series relative to control over 18 quarters of testing indicates that acute effects are not likely in groundwater discharge that is diluted by 50 percent or greater by surface water in the Flathead River. These findings are consistent with the MDEQ Statement of Basis that accompanied the 1999 MPDES Permit No. MT-00330066 (MDEQ, 1999), which previously authorized the discharge of groundwater to the Flathead River, including the Backwater Seep Sampling Area, from 1994 through April 17, 2019. The MDEQ Statement of Basis indicated no anticipated impacts on aquatic species or other species (**Section 3.3.3)**.

As previously stated in **Section 3.3.3**, the section of the Flathead River that includes the Backwater Seep Sampling Area has limited fish habitat for common species and is primarily used as a migration corridor to access areas of more suitable habitat (Stagliano, 2015). As a result, fish exposure to cyanide in surface water in the Backwater Seep Sampling Area is likely spatially-limited near points of groundwater discharge and temporally-limited to exposure during migration. Further, the lack of spawning or nursery habitat in the reach of the Flathead River near the Site limits exposure to early life stages that may have greater sensitivity to exposure. These findings are consistent with the MDEQ Statement of Basis that accompanied the 1999 MPDES Permit No. MT-00330066 (MDEQ, 1999), which indicated that area of exceeding acute cyanide standards would not inhibit fish migration and that there were no impacts to spawning or nursery areas or attraction to cyanide within the mixing zone (**Section 3.3.3)**. Subadult bull trout and other native fish may increasingly use channel margin habitat like that of the Backwater Seep Sampling Area during periods of increased flows (David Rouse, U.S. Fish and Wildlife Service, information received in agency comments on the Draft BERA). However, this period of increased flows is limited in duration (typically greater than the 90th percentile discharge rate from April to June; see **Figure 3-5**) and coincides with lower cyanide exposure concentrations in surface water resulting from dilution by increased surface water discharge in the Flathead River (**Figure 6-35**).

The results of toxicity testing indicate low potential for acute effects to fish and aquatic invertebrate test organisms resulting from exposure to cyanide and COPECs in surface water in the Backwater Seep Sampling Area. However, it should be noted that WET testing results represent a snapshot of exposure that may not capture the temporal variability in the toxicity of groundwater discharge in the Backwater Seep Sampling Area. Further, the dynamic environmental conditions that control the fate of toxic forms

of cyanide (see **Section 3.3.7.1**) present *in situ* within the Backwater Seep Sampling Area may not be adequately represented in *ex situ* toxicity tests conducted in a laboratory. In addition to these uncertainties regarding acute effects, there is uncertainty in potential chronic, direct contact effects to aquatic and benthic receptors exposed to cyanide in the spatially-limited area of the Backwater Seep Sampling Area that receives ongoing inputs from groundwater discharge. Free cyanide is not expected to persist in surface water due to photodegradation and volatilization (MDEQ, 1999) or in sediment based on limited partitioning (Higgins and Dzombak, 2006); however, potential input from shallow groundwater may be an ongoing pathway to pore water and *in situ* dissociation of metal-cyanide complexes may be an ongoing source of free cyanide in surface water within the Backwater Seep Sampling Area. These conditions result in exceedances of acute and chronic NRWQC for free cyanide and acute and chronic DEQ-7 criteria for total cyanide in samples collected from stations within the Backwater Seep Sampling Area (CFSWP-003 through CFSWP-005). As demonstrated by the temporal analysis presented above, the greatest exposure to cyanide in this area likely occurs during low discharge periods within the Flathead River.

As discussed in **Section 6.3.1.2**, the wildlife ingestion model indicated that HQ_{NOAEL} values for vanadium and PAHs exceeded 1, but no HQ_{LOAEL} values exceeded 1. Elevated cyanide concentrations detected in surface water within the Backwater Seep Sampling Area were evaluated in the screening-level wildlife ingestion model using a worst-case scenario in which modeled receptors were assumed to ingest drinking water with the greatest detected cyanide concentration (378 µg/L) 100 percent of the time. The results of this model indicated that the maximum HQ_{NOAEL} based on ingestion of cyanide in drinking water was 1.57 for the American Dipper based on chronic TRVs (see **Appendix H1; Table H12-2**). The maximum HQ_{NOAEL} for cyanide based on dietary, incidental sediment ingestion, and drinking water exposure pathways was slightly higher (HQ = 2.26) for the American Dipper. HQ_{LOAEL} values were well below 1 for summed pathways for each receptor based on chronic TRVs. The risk modeled using the chronic cyanide TRVs is protective of acute risk, as evidenced by the fact that the avian TRV was developed by dividing an acute LD_{50} TRV endpoint by 100 to derive the chronic TRV (LANL, 2017). Because cyanide is rapidly metabolized and does not bioaccumulate (USEPA, 1985), adverse effects to semi-aquatic wildlife potentially foraging in or ingesting surface water exclusively in the Backwater Seep Sampling Area are also not likely. Therefore, potential risks associated with direct and incidental wildlife ingestion pathways are considered to be minimal.

6.3.2 Flathead River Riparian Area Channel

Risk estimates and the baseline risk characterization for direct contact and ingestion exposure pathways are presented below for the Flathead River Riparian Channel.

6.3.2.1 Direct Contact Risk Estimate

Direct contact risk estimates for sediment indicate that the greatest exposure in the Riparian Channel is associated with sampling stations near the Backwater Seep Sampling Area. Risk estimates for benthic invertebrates indicate that maximum concentrations are below NOECs for all COPECs, except total cyanide, barium, and ∑ESBTU values (**Table 6-49**); the maximum concentration of total cyanide was the only concentration exceeding its benthic invertebrate LOEC (HQ_{LOEC}=1.7). The maximum cyanide concentration and maximum ∑ESBTU value were observed at stations CFSDP-29 and CFSDP-30, respectively (**Figure 6-38**). Refined concentrations did not exceed LOECs, except for a slight exceedance of total cyanide (HQ_{LOEC}=1.1). Pore water concentrations of free cyanide exceeded the chronic NRWQC-

based NOEC at 3 of 5 stations (maximum HQ_{NOEC}=7.4) and acute NRWQC-based LOEC at 2 of 5 stations (maximum HQ_{LOEC}= 1.8 at station CFPWP-029) (**Figure 6-38; Table 6-50**). Total cyanide concentrations exceeded the DEQ-7 chronic NOEC and acute LOEC at all five stations (maximum HQ_{NOEC} = 82.5 and maximum HQ_{LOEC}= 19.5 at station CFPWP-029). Maximum barium concentrations exceed NOECs and LOECs (HQ_{LOEC}=10.1). Maximum concentrations of PAHs in pore water were lower than NOECs, indicating limited bioavailability and exposure to PAHs in the Flathead Riparian Area Channel.

The greatest direct contact exposure to COPECs in surface water within the Flathead Riparian Area Channel was associated with stations adjacent to the Backwater Seep Sampling Area and the South Percolation Ponds. Maximum concentrations of total cyanide, free cyanide, fluoride, aluminum (unfiltered), and copper (unfiltered) exceeded NOECs and LOECs (**Table 6-51; Table 6-52**). Maximum concentrations of cyanide (total and free) were observed at Station CFSWP-029, located at the eastern edge of the Backwater Seep Sampling Area (**Figure 6-39**), resulting in HQ_{LOEC} values in unfiltered samples ranging from 28.6 (total cyanide) to 6.4 (free cyanide); refined concentrations resulted in HQ_{LOEC} values in unfiltered samples ranging from 15.6 (total cyanide) to 2.8 (free cyanide; **Table 6-51**). Unfiltered aluminum concentrations exceeded sample-specific NOECs in 6 of 15 samples, with HQ_{NOEC} values ranging from 1.2 to 41.6 (**Table 6-52**); unfiltered aluminum concentrations exceeded sample-specific LOECs in 3 of 15 samples (HQ_{LOEC}=1.8 to 10.7; **Table 6-52**). Filtered aluminum concentrations were below NOECs. Unfiltered copper samples exceeded NOEC and LOEC values in 2 of 15 samples (HQ_{LOEC} =1.0 to 2.0; **Table 6-52**). Maximum and refined concentrations of barium (unfiltered and filtered) exceeded LOECs, with HQ_{LOEC} values for maximum and refined concentrations in filtered samples of 10.3 and 6.9, respectively (**Table 6-51**).

6.3.2.2 Ingestion Risk Estimate

The samples in the Flathead River Riparian Area Channel were collected specifically to more fully characterize the impacts of seep and groundwater influence on the Flathead River. Data from these samples were not included in the food chain model used to estimate potential risk associated with direct and indirect ingestion of constituents in various media. Thus, ingestion risk estimates were not developed for the Flathead River Riparian Area Channel.

6.3.2.3 Risk Characterization

The evaluation of sediment and surface water data in the Flathead River Riparian Channel indicate the potential for adverse effects associated with exposure to cyanide (total and free), fluoride, and metals in surface water. Benthic invertebrate exposure to COPECs in sediment was limited to exposure to total and free cyanide, barium, and a $\sum ESBTU_{FCV,Total}$ value exceeding 1.0 at one of five stations. Exposure to cyanide (total and free) and barium in sediment is associated with aqueous exposure in pore water. Free cyanide is not expected to persist in sediment based on limited partitioning (Higgins and Dzombak, 2006); however, potential input from shallow groundwater appears to be an ongoing pathway to pore water in the Flathead River Riparian Channel. Free and total cyanide concentrations in pore water samples exceeded NRWQC and DEQ-7 chronic (NOECs) and acute (LOECs) criteria. Low PAH concentrations measured in pore water indicate low PAH bioavailability and minimal potential for adverse effects.

Surface water data indicate potential exposure to COPECs may be influenced by groundwater discharge associated with the Backwater Seep Sampling Area and surface discharge from the South Percolation Pond Area. As stated in **Section 6.3.1.3**, the results of surface water toxicity testing in the Backwater

Seep Sampling Area did not indicate a significant acute effect on the survival of Ceriodaphnid and Fathead Minnow test organisms exposed to cyanide and other COPECs associated with groundwater discharge that was diluted by 50 percent or greater in test chambers (**Section 6.3.1.3)**. However, there is uncertainty in potential chronic direct contact effects to aquatic and benthic receptors in the Flathead Riparian Area Channel that may be exposed to cyanide and other COPECs through ongoing inputs from groundwater discharge. As demonstrated by the temporal analysis presented in **Section 6.3.1.3**, the greatest chronic exposure to cyanide in Flathead Riparian Area Channel likely occurs during periods of elevated discharge within the Flathead River (**Figure 6-35**).

6.3.3 Cedar Creek

Risk estimates and the baseline risk characterization for direct contact and ingestion exposure pathways are presented below for the Cedar Creek.

6.3.3.1 Direct Contact Risk Estimate

Direct contact risk estimates for aquatic receptors inhabiting Cedar Creek indicate minimal potential for adverse effects for benthic invertebrates exposed to cyanide, metals, and PAHs (**Table 6-53**). Maximum concentrations of COPECs in sediment resulted in minor exceedances of NOECs for cyanide (HQ_{NOEC}=2.4), barium (HQ_{NOEC}=1.7), manganese (HQ_{NOEC}=1.2; **Table 6-53**). $\sum ESBTU_{34}$ values slightly exceeded 1.0 at one station ($\sum ESBTU_{34}$ = 1.3). Refined concentrations exceeded NOECs only for total cyanide (HQ_{NOEC}=1.6) and barium (HQ_{NOEC}=1.1). PAHs were not detected in pore water; barium and manganese were the only COPECs detected in pore water at concentrations exceeding LOECs (**Table 6-54**). Barium concentrations in pore water remain consistent in samples collected from the upstream station in Cedar Creek (CFPWP-014) to the most downstream Cedar Creek station (CFPWP-016; **Figure 6-40**). This indicates that barium concentrations in pore water may be associated with regional conditions and not related to pathways from the Site.

Direct contact aqueous risk estimates indicate negligible potential for adverse effects associated with surface water exposure to cyanide and barium (**Table 6-55**). Maximum total and free cyanide concentrations exceeded the DEQ-7 based NOEC for total cyanide and NRWQC based NOEC for free cyanide resulting in HQ_{NOEC} values of 2.9 and 1.5, respectively. However, cyanide (free and total) did not frequently exceeded chronic NOECs in surface water samples collected from Cedar Creek. Free cyanide was detected in 2 of 20 samples and exceeded the NRWQC based NOEC in 1 of 20 samples. Total cyanide was detected in 7 of 22 samples and exceeded the DEQ-7 based NOEC in 2 of 22 samples. Maximum concentrations of barium in surface water samples exceeded the NOEC and LOEC (HQ_{LOEC} 3.0 to 3.3). Barium concentrations in surface water samples were consistent upgradient to downgradient and during the multiple sampling events (**Figure 6-41**). Further, barium concentrations in surface water are comparable to the BTV calculated from upgradient filtered samples off-site in Cedar Creek (99.8 µg/L; Roux, 2019). These findings indicate that direct contact exposure within the Cedar Creek is consistent with regional conditions and not associated with site-related pathways.

6.3.3.2 Ingestion Exposure Estimate

The screening-level food ingestion model that assumed 100 percent exposure to surface water and sediment in Cedar Creek and used maximum concentrations as the EPCs resulted in HQ_{NOAEL} that slightly exceeded 1 (1.1) for the American Dipper exposed to barium (**Table 6-57**) (**Appendix H**).

The results of the refined food chain model using more realistic assumptions were similar, with the American dipper having an HQ_{NOAEL} that slightly exceeded 1 (1.06) for barium. No HQ_{LOAEL} values exceeded 1 (**Table 6-56**). Barium in Cedar Creek sediment was found to be comparable to background in the comparison of populations to upgradient reference area sediment data (Roux, 2019). Thus, ecological risk to wildlife associated with direct and indirect ingestion of media in Cedar Creek is considered minimal.

6.3.3.3 Risk Characterization

Potential risks associated with direct contact with surface water and sediment in Cedar Creek are considered to be negligible. Cyanide (free and total) did not frequently exceeded chronic NOECs in surface water samples collected from Cedar Creek over multiple sampling events. Maximum concentrations of barium in surface water exceeded NOECs and LOECs in some samples, but the magnitude of exceedance was low, and no other constituents had EPCs that exceeded LOECs. No constituents in sediment were detected at concentrations that exceeded their LOECs. Pore water concentrations exceeded their LOECs for barium and manganese, but the HQ for manganese did not exceed 1 when rounded. Barium concentrations in surface water and pore water are consistent upgradient to downgradient, suggesting that concentrations are representative of upgradient/background conditions. Also, the concentrations in surface water (mean = 99.7 µg/L, refined EPC = 105 µg/L for filtered barium) and pore water (mean = 146 µg/L, maximum = 269 µg/L for filtered barium) were comparable to the upgradient reference area concentrations in Cedar Creek (mean = 91 µg/L, BTV = 99.8 µg/L for filtered barium), which indicates that concentrations of barium within Cedar Creek is consistent with regional conditions and not associated with site-related pathways.

Barium concentrations resulted in an HQ_{NOAEL} for the American Dipper that slightly exceeded 1 (1.1) for barium, but no HQ_{LOAEL} values exceeded 1. As discussed in the previous paragraph, barium in Cedar Creek surface water was comparable to background levels. Therefore, ecological risk to wildlife associated with direct and indirect ingestion of media in Cedar Creek is considered minimal.

7 Uncertainty Analysis

A critical component of the BERA is the analysis of uncertainty that is inherent in the ERA process. A thorough uncertainty analysis is necessary to understand how potential uncertainty may affect the risk estimates and associated risk characterization that may be used to support risk management decision-making.

7.1 Adequacy, Representativeness, and Quality of Sampling Data

The BERA was performed using a dataset that was compiled during multiple investigation phases. Phase I data were collected in 2016 and 2017. Additional data was collected during the Supplemental South Pond Assessment in late 2017, and the Phase II data were collected in 2018. The use of data from samples collected during three separate field mobilizations allowed for an evaluation of the Phase I data and the development of a follow-on sampling strategy designed to address any data gaps or uncertainties revealed by earlier sampling events. The Phase II sampling effort was designed to provide (along with Phase I data) a comprehensive data base that would provide confidence in any decisions and recommendations generated by evaluations based upon it. To accomplish this goal, the objectives of the Phase II effort were to address data gaps in the Phase I data and provide additional critical information regarding the characterization, nature and extent, bioavailability, fate and transport, and toxicity of possible COPECs associated with historical source areas. The strategy for accomplishing this was provided in the Phase II SAP (Roux, 2018a), which was reviewed and approved by project stakeholders. Data quality was reviewed and determined to be acceptable in the Phase I and Phase II Data Summary Reports (Roux 2017a, 2019). Therefore, the adequacy, representativeness, and quality of the sampling data is judged to be adequate for Site decisions regarding ecological exposure at the facility.

USEPA and MDEQ review of the Phase II DSR indicated that the report was clear, detailed, and complete, and generally contains the data needed to complete the risk assessments and feasibility study. Should additional investigations or actions be necessary in areas where unacceptable ecological risk is identified, the need for additional sample collection for the purposes of further delineation characterization, or risk management will be evaluated and discussed in the Feasibility Study for specific COPECs and exposure pathways that have been identified for risk management at the Site.

7.2 Temporal (Seasonal) Variability in Exposure

Temporal variability contributes to variability in ecological exposure conditions at the Site, particularly with regards to the exposure pathway between groundwater and seep/surface water entering the Flathead River. Phase I data provided some information regarding river stage and seasonality on the variability of key COPECs such as cyanide and fluoride and their discharge rates into surface water bodies. The Phase II sampling effort provided additional data to further refine the relationships between surface water COPEC concentrations and hydrology during various times of the year. Sediment samples from the Flathead River exposure area (including the Backwater Seep Sampling Area) were collected during low flow periods exclusively, when the Flathead River would most likely be acting as a gaining stream. An approximately equal number of surface water samples were collected during low (41 samples) and high flow (36 samples) hydraulic conditions (see **Table 4-12**). Thus, sediment results for this exposure area are expected to be conservative, and surface water results are expected to reflect year-round exposure. However, it is noted that the maximum EPCs used in the screening-level wildlife exposure models represent the maximum seasonal exposure scenario. The temporal evaluation

presented in **Section 4.1.2.2** indicates that surface water sampling conducted during Phase I and Phase II investigations comprise a wide range of hydrologic conditions that effectively capture the temporal variability of exposure conditions that are influenced by surface water discharge (**Figure 3-5**). Therefore, uncertainty associated with temporal/seasonal variability in exposure has largely been addressed in the BERA.

Another seasonal influence on ecological exposure and risk involves the seasonal inundation of some low-lying or seep-influenced portions of the site. These areas were evaluated as transitional exposure areas in the BERA, and complete evaluations were performed assuming that conditions were both dry (during which terrestrial exposure scenarios were evaluated) and wet (during which semi-aquatic exposure scenarios were evaluated). By evaluating both scenarios assuming the site conditions were inundated or dry 100 percent of the time, the BERA provides a conservative evaluation of both terrestrial and semi-aquatic exposure (i.e., no temporal adjustment was used to "dilute" one scenario or the other by assuming that exposure only occurred part of the time).

7.3 Exposure to Pathways Not Included in the BERA

The pathways evaluated in the BERA are intended to capture a majority of the potential exposure to constituents in relevant media. However, constituents can enter organisms from a multitude of pathways, not all of which can be fully quantified in a risk assessment. Studies have shown that ingestion and direct contact are the most significant pathways, but other modes of exposure into a receptor are possible. Not quantifying risk associated with those pathways could result in an underestimation of total risk. Perhaps the most potentially significant pathways not evaluated in the risk assessment are dermal exposure and inhalation of COPECs. Dermal and inhalation exposure routes for wildlife are typically not addressed because they are considered minor relative to ingestion, and due to the lack of science supporting the evaluations. Dermal exposure is assumed to be negligible for birds and mammals due to the presence of fur and feathers. Dermal contact to amphibians and aquatic organisms is considered through the use of protective water quality and sediment benchmarks that are inclusive of this route of exposure. Some circumstances may exist where dermal and inhalation exposure may be significant, such as for burrowing wildlife and those species that inhabit burrows of others. However, based on COPEC fate and transport considerations, it is unlikely that risk from inhalation exposure is significant at the Site. Constituents that are most likely to volatilize to the air (i.e., VOCs) are not the primary COPECs at the site and were generally detected at trace concentrations in site media, and only six VOCs were identified as COPECs across all exposure areas. Therefore, it is unlikely that ecological risk was significantly underestimated by the absence of quantified risk associated with dermal or inhalation exposure pathways.

7.4 Potential Exposure to Constituents Not Detected in the Datasets

The sampling locations and analytical methods used to collect environmental data at the Site were described in detail in various work plans reviewed and approved by regulatory agencies. The sampling and analysis strategy was designed to target areas where known or suspected waste streams associated with plant operations may have impacted environmental media. A sensitivity analysis was performed prior to the sampling effort to ensure, to the extent possible, that the analytical methods employed were sensitive enough to detect constituent concentrations associated with potential adverse effects to ecological receptors. However, 100 percent attainment of this objective was not achieved, and some constituents that were not detected in any samples had detection limits that exceeded protective

benchmarks, resulting in some uncertainty regarding their presence at concentrations that are undetectable, yet potentially toxicologically significant. This source of uncertainty was discussed in the COPEC selection uncertainty analysis (**Section 4.6**), where it was concluded that this was a minor source of uncertainty that was highly unlikely to affect BERA conclusions.

7.5 Potential Exposure to Constituents Lacking Ecotoxicity Data

Toxicity data that allow for a quantitative assessment of risk are not available for some constituents. The COPEC selection uncertainty section (**Section 4.6**) discussed constituents that lacked ESVs and concluded that the lack of ESVs was unlikely to affect BERA conclusions, as the constituents most likely to adversely affect ecological receptors detected in site media did have ESVs that could be used to help determine if the constituent should be carried forward for further evaluation. The risk characterization portion of the BERA utilized TRVs as benchmark values to assess if modeled doses to various receptors exceeded no-observed and lowest-observed effect doses. However, several constituents identified as COPECs with the potential to bioaccumulate lacked TRVs, including antimony (birds), and dibenzofuran (birds and mammals). Antimony was identified as a COPEC in several exposure areas, but dibenzofuran was only a COPEC at the Central Landfills Area and the North Percolation Pond Area. Dibenzofuran was identified as a potentially bioaccumulative constituent because its log K_{ow} slightly exceeds the criterion of 3.5 (3.7). The presence of dibenzofuran at the North Percolation Pond Area is somewhat irrelevant due to the number of constituents identified as likely risk drivers in that exposure area. At the Central Landfills Area where estimated risk due to ingestion pathways was much less definitive, the presence of dibenzofuran represents a minor uncertainty. Dibenzofuran was detected in approximately half (52 of 110) soil samples at concentrations ranging from 0.0016 mg/kg to 15 mg/kg. Because it was detected frequently in site soil at concentrations that do not resemble a gradient consistent with pathways from site source areas, the presence of dibenzofuran in soil at the Central Landfills Area is unlikely related to a release and is a minor uncertainty in the BERA.

For the direct contact evaluation, NOEC/LOEC data were unavailable for some constituents. Perhaps the greatest uncertainty was the lack of soil and surface water LOEC for benchmarks for PAHs, which were a primary COPEC at many exposure areas. LOECs help to bound site risks and can provide a level above which the potential ecological risk becomes more likely. However, bulk concentrations in media and comparison to NOECs (including considering the magnitude of exceedance) provided sufficient information in most cases to determine whether PAHs should be candidates for additional action within a given exposure area. Therefore, the uncertainty associated with the lack of LOECs for PAHs is not substantial.

Two nutrients, calcium and sodium, were detected at elevated concentrations in site media, but additional toxicity data to assess potential impacts to ecological receptors are lacking. Calcium may be related to historical Site processes due to its association with fluorite, which is a component of feedstocks used in smelting. Calcium was detected at elevated concentrations that exceeded the range of BTVs from multiple background reference areas by an order of magnitude. However, the maximum concentration detected at the Site (313,000 mg/kg) was within the concentration range observed in Western U.S. soils (maximum = 320,000 mg/kg). Furthermore, the range of means detected within the multiple exposure areas at the Site (8,152 mg/kg to 125,544 mg/kg) were well within the range of concentrations of Western U.S. soils. Thus, the average concentration experienced at any exposure area is less than half the upper limit of naturally occurring calcium concentrations in western soil. The highest mean and maximum concentrations of calcium in soil/sediment were within the South Percolation Pond

Area (mean = 125,543 mg/kg). The Flathead River Riparian Area, which surrounds the South Percolation Pond, had mean (20,260 mg/kg) and maximum (41,600 mg/kg) concentrations of calcium approximately an order of magnitude lower than the South Percolation Pond. Therefore, although calcium is elevated in the South Percolation Pond, these elevated concentrations are relatively isolated, and are within the upper limits of naturally occurring calcium in the western U.S. Therefore, the inability to quantify risk associated with elevated calcium in soil at the Site represents a relatively minor uncertainty.

Sodium and calcium were detected at elevated concentrations compared with background in unfiltered and filtered surface water samples. The greatest sodium and calcium concentrations in surface water were associated with sampling stations in exposure areas where groundwater discharge is a potential migration pathway: the Flathead River within the Backwater Seep Sampling Area, Flathead Riparian Area Channel, South Percolation Pond Area, and the Northern Surface Water Feature. Elevated sodium and calcium concentrations in surface water samples from these features is consistent with elevated sodium concentrations observed in groundwater wells screened within the upper hydrogeologic unit at the Site, which are indicative of the potential groundwater discharge pathway (Roux, 2019). Sodium is a possible constituent of historical waste streams due to its presence as sodium cyanide (NaCN). This cyanide salt is highly soluble, which is consistent with the presence of much more highly elevated concentrations of sodium in groundwater and surface water than in soil at the Site.

7.6 Selection of Substitution Value for Non-Detected Results

HMW/LMW/Total PAHs and TEC calculations for dioxins were performed using multiple substitution strategies for non-detected results to bracket the range of potential concentrations that might be present in the sample. For both PAHs and dioxins, values of zero, one-half the MDL, and the full MDL were used as surrogate values for non-detects. In no situation did the selection of the substitution method affect whether or not the constituent grouping was selected as a screening or refined COPEC (**Appendix B** and **Appendix E**). Therefore, the selection of the substitution value for non-detect resulted in little to no uncertainty for this BERA.

7.7 Background Evaluation Methods

The approaches used in the BERA to determine what constituents were related to natural or ambient environmental conditions imparted a highly conservative bias to the evaluation. The comparison of the exposure area UCL to the mean concentration in background samples at the COPEC refinement stage (**Section 4.4.2**) resulted in very few constituents being eliminated from further consideration, even in areas that are unlikely to be impacted by previous site activities. For example, in the Eastern Undeveloped Area, North-Central Undeveloped Area, and Western Undeveloped Area, only two metals were eliminated from further consideration due to this comparison to background. The second phase of the background evaluation consisted of a hypothesis test that statistically compared the site and background datasets to determine whether they were from the same or different populations. The Background Test Form 2 was used for this evaluation, which states as its null hypothesis that the mean COPEC concentration in samples from the exposure area is greater than the sum of the mean concentration in the respective background area and the substantial difference (Roux, 2018b). Test Form 2 requires a stricter burden of proof because instead of using a null hypothesis that the mean or median concentration of the potentially impacted site area does not exceed the mean or median of background, the null hypothesis that must be “disproven” is that the mean or median of the site exceeds the mean or median of background by a specified amount. Therefore, the use of the Test Form

2 is more protective of the environment by requiring that the data contain evidence of no substantial contamination (EPA, 2015b). However, the use of this test form also increases the chance of a Type II error, or failing to reject the null hypothesis, which in this case is that site concentrations are present above background concentrations. Thus, the use of the Test Form 2 likely resulted in identifying some constituents at the various exposure areas as being significantly greater than background when no statistically significant difference in populations actually exists.

7.8 Appropriateness of Variables Used in the Dose Rate Models

The variables used in the dose rate models that estimated risks associated with direct and indirect ingestion of COPECs to wildlife, including exposure parameters, TRVs, and AUFs, were documented and submitted for regulatory review in the *Technical Memorandum: Proposed Wildlife Exposure Modeling Approach to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site* (presented in **Appendix A2**) prior to the initiation of the BERA. Selected variables were obtained from general literature sources and compilations of exposure factors developed to support dietary exposure modeling and were intended to reflect a conservative, but not worst-case estimate of exposure and toxicity. For example, mean body weights were used in the food chain modeling, but maximum and UCL_{mean} concentrations were used as initial and refined EPCs, respectively. AUFs used to adjust exposure based on the portion of the affected area that occurs within the home range of the receptor was not considered during the screening evaluation but was incorporated into the refined version of the model. When AUFs were used, contributions of risk from areas outside of the target exposure area were not assumed to be zero; rather, the spatially weighted contributions of COPECs from adjacent exposure areas within the receptor home range were added to estimate the aggregate risk. Finally, both NOAEL and LOAEL TRVs were used to provide context for the potential toxicity of doses incurred by the various receptors.

The use of conservative assumptions (i.e., the use of the maximum EPC and an AUF of 1) in the screening-level wildlife ingestion model combined with the more representative exposure assumptions utilized in the refined models provides sufficient information for decision making at the Site. Because of overall conservativeness of the assumptions and variables used throughout the BERA process, the likelihood of underestimating risk is low. Rather, risk estimates are likely to be overestimated at this stage of the BERA. If additional studies are performed (e.g., site-specific toxicity or uptake studies), the uncertainty associated with this (likely) overestimation may be reduced.

7.9 Uncertainty Associated with the HQ Method of Estimating Risk

Risk estimation was performed through a series of quantitative HQ calculations that compare receptor-specific exposure values with TRVs. HQs are compared to HQ guidelines for assessing the risk posed from COPECs. It should be noted that HQs are not measures of risk, are not population-based statistics, and are not linearly scaled statistics. Therefore, an HQ above 1, even exceedingly so, does not definitively indicate that there is a single organism adversely impacted by the toxicological effect associated with a given constituent to which it was exposed currently or in the future (Tannenbaum, 2005; Bartell, 1996). HQs exceeding 1 only suggest that the potential for adverse hazard may exist, and the probability of adverse effects occurring may increase with increasing HQ magnitude.

7.10 Uncertainty Associated with AVS-SEM Results

As described throughout the BERA (e.g., Sections 3.6 and 4.1.3, etc.) and in the Phase II Sampling and Analysis Plan (Roux, 2018a), AVS-SEM data were collected as part of the Phase II site characterization effort in sediments where divalent metals were suspected or known to be present at concentrations above ESVs based on total recoverable metal analyses. As stated in **Section 3.3.7.4**, the soluble phase of metal ions in sediment pore water is generally the most bioavailable and potentially toxic form to ecological receptors. Equilibrium partitioning theory may be used to predict the bioavailability toxicity of metals in sediment based on the partitioning of SEM between AVS, TOC, and pore water (USEPA, 2005a). In reduced sediments, free metal ions partition to AVS and TOC to form insoluble metal sulfide complexes that have low bioavailability and are associated with low toxicity to benthic organisms in toxicity tests (USEPA, 2005a). Based on this principle, AVS-SEM and TOC data were used in the BERA in conjunction with pore water data to provide multiple lines of evidence to evaluate the bioavailability of divalent metals in sediments in select exposure areas at the Site.

A study performed by Hammerschmidt and Burton (2010) identified potential issues with the reproducibility of AVS-SEM results between laboratories, indicating some uncertainty with AVS-SEM results as the basis for decision-making. The study examined AVS-SEM results for sediment subsamples that were distributed to seven independent laboratories and found varied results (ranging from 70 to 3,500-times for AVS and 17 to 60-times for SEM) owing to varying laboratory preparations, detection limits, and other factors. The information presented in Hammerschmidt and Burton (2010) indicates some uncertainty regarding the accuracy and replicability of AVS-SEM data between laboratories. However, the additional pore water line of evidence collected as part of the Phase II site characterization limits the uncertainty associated with AVS-SEM results. Given that multiple lines of evidence were evaluated in the assessment of metal bioavailability in sediment, the uncertainty associated with AVS-SEM analyses is not likely to affect overall conclusions regarding potential metal toxicity to benthic organisms at the Site

7.11 Calculation of HQs for Large Home Range Receptors

As discussed in **Section 5.3.3.2.1**, low-level contributions from adjacent exposure areas that resulted in an HQ_{NOAEL} of less than 1 for that exposure area were not included in the spatially weighted HQ calculations for large range receptors. This results in a slight underestimation of the aggregate dose for receptors foraging in multiple exposure areas. However, because contributions from adjacent exposure areas are spatially weighted, their impacts on the target exposure area are reduced proportionally by the percent of the receptor home range they occupy. For example, if target Exposure Area A had an HQ for lead of 2 and comprised 60 percent of the receptor home range, and Exposure Areas B, C, and D each had HQs for lead of 0.9 and comprised 10 percent of the receptor home range, the spatially weighted HQ would be (2 x 0.6) + (0.9 x 0.1) + (0.9 x 0.1) +(0.9 x 0.1) + (0.9 x 0.1) = 1.56, compared to an HQ of 1.2 if Exposure Areas B, C, and D were assumed to contribute HQs of 0. Therefore, the spatially weighted HQs for large range receptors are recognized as having some uncertainty due to a slight non-conservative bias associated with this approach, but the uncertainty is not considered significant enough to warrant recalculation of HQs or affect the conclusions presented in this BERA.

Furthermore, any area within the foraging range of a large-range receptor that was outside of the Site boundary was not included in the spatially- weighted HQ calculation, effectively adding a dose of zero for that percentage of the home range outside the Site. This approach assumes that background levels contribute de minimus risk, which is consistent with the practice of excluding constituents detected on-

site that are naturally occurring in the COPEC refinement step. In other words, if copper in soil within the exposure area was found to be background-related, it was not included in the wildlife ingestion model, which would essentially result in a dose of zero for copper in that exposure area. Therefore, both on- and off-site background-related risk was assumed to be negligible in this BERA and was not included in the wildlife ingestion modeling. The practice of assuming a dose of zero (rather than background) may slightly underestimate risk by not accounting for contributions from non-site related sources.

7.12 Incremental and Discrete Soil Sample Results in the Operational Area

As described in **Section 5.3.1**, both ISS and discrete soil samples were collected within the Operational Area, which overlaps portions of both the Main Plant and Central Landfills ecological exposure areas. The ISS samples were evaluated on an individual DU basis and used to evaluate potential impacts to sessile and small-range receptors, while the discrete samples were used in the exposure area-wide ingestion dose-response model that was used to evaluate receptors with a variety of home range sizes. Four DUs within the Operational Area grid were sampled in triplicate. RSDs calculated for each chemical and depth interval from these triplicate results were used to adjust the concentrations in the non-triplicate DUs to account for potential variability associated with the ISS samples (**Section 4.1.1.1)**. The high-adjusted concentrations were used in the screening-level and refined COPEC selection process (**Sections 4.3.2** and **4.5.2**), as well as the risk characterization for the Operational Area (**Section 6.3.1**). The range of mean RSDs used to adjust the non-triplicate DUs was 2.8 percent to 139 percent for the 0 to 0.5-ft bgs interval, and 1.9 to 98.2 percent for the 0.5 to 2 ft bgs interval. 20 of 60 mean RSDs used to adjust the concentrations in the 0 to 0.5-ft bgs interval exceeded 35 percent, and 31 of 62 in the 0.5 to 2 ft bgs interval exceeded 35 percent. Consistent with ITRC guidance (ITRC, 2012a), a criterion of 30 to 35 percent RSD in field replicates within the triplicate ISM DUs may indicate substantial heterogeneity in constituent concentrations within the DU. However, the fact that this criterion was exceeded for several individual and averaged RSD estimations did not materially affect risk conclusions in the BERA. Only one additional non-PAH SVOC was identified as a screening-level and refined COPEC using the high-adjusted dataset compared to the measured and low-adjusted datasets (**Appendices B** and **E**). The results of the risk characterization for the Incremental Sampling Grid (**Section 6.1.3**) were reviewed, and, although HQs were somewhat greater than if they had been based on the measured EPC dataset, the use of the high-adjusted values also did not materially affect results for the direct contact or small home range receptor evaluation (e.g., identification of additional site-related constituents with HQs > 1). Therefore, the variation within the triplicate results is noted as an uncertainty in the BERA, but the impacts on the BERA conclusions are minimal. Any impacts associated with this noted variation are conservative, as the high variance resulted in higher UCLs for the DUs with triplicate results, and in higher EPCs for the non-triplicate DUs, which collectively were used as the basis for COPEC selection and risk characterization.

A comparison was performed between the concentrations detected in ISS samples collected in the Main Plant Area and Central Landfills Area and the discrete soil samples that were collected within the ISS grid in these two ecological exposure areas to determine whether the discrete samples collected from these portions of the areas were appropriately representative of exposure to large-range receptors evaluated in the wildlife ingestion model.

The comparison between ISS and discrete sample concentrations was performed on constituents that were identified as refined COPECs for the Main Plant Area and Central Landfills Area (see COPEC refinement tables in **Appendix E**). Summary statistics, including detection frequency and the minimum,

mean, and maximum detected concentrations, were compiled for the ISS samples (including both the 0-0.5 bgs and the 0.5-2 ft bgs sampling depths) and the discrete samples (0-2 feet bgs) that were nested within the ISS grid footprint in both exposure areas. The ISS results used for this comparison were the calculated 95 percent UCLs for DUs with triplicate results and the measured (i.e., unadjusted) concentrations from the DUs lacking triplicate results. The results are presented in **Table 7-2**. Box and whisker plots for select metals, other inorganic constituents (i.e., cyanide and fluoride), and PAHs are presented in **Figures 7-1, 7-2**, and **7-3**, respectively.

Most metals and both LMW and HMW PAHs had higher average concentrations in the ISS samples compared to the discrete samples that were collected within the ISS grid footprint compared to the discrete samples (**Table 7-2**; **Figures 7-1** and **7-3**). Cyanide and fluoride in the Main Plant Area, and fluoride in the Central Landfills Area also had higher mean concentrations in the ISS compared to discrete soil samples; although the mean concentration of cyanide in ISS samples was slightly lower than discrete samples, the median and overall distribution of cyanide concentrations was greater in the Central Landfills Area (**Table 7-2**; **Figure 7-2**) . Some of the differences were substantial; for example, copper, selenium, and zinc in the Main Plant Area, the mean concentration among the ISS samples was 4.8-, 5.5-, and 3.7-times the mean of the discrete samples. Copper, lead, and selenium in the Central Landfills Area had mean ISS concentrations more than twice as high as the discrete samples from the ISS grid footprint. Mean LMW and HMW PAHs ranged from 1.3 to 2-times higher in the ISS samples compared to the discrete samples across both exposure areas (**Table 7-2**).

The results of this evaluation indicate that the estimated doses for larger range receptors that were calculated using discrete samples may be somewhat underestimated in the portions of the Main Plant Area and Central Landfills Area that overlap the ISS grid. However, because this area comprises only a portion of most receptor home ranges, the impacts of this underestimation would be ameliorated by the remainder of the exposure area. A summary of the percentage of the home range of each terrestrial receptor that falls within the ISS grid for the Main Plant Area and Central Landfill Area is provided in the following table (note that the meadow vole and short-tailed shrew are small range receptors that are evaluated on a sample-by-sample basis for both ISS and discrete soil samples, and are not shown in the table):

Terrestrial receptor	Home Range (acres)	# of Approx. 1-acre grids in Main Plant Area	% of Home Range	# of Approx. 1-acre grids in Central Landfill Area	% of Home Range
American Woodcock	11.1	14	126%	29	261%
Mourning Dove	1986	14	1%	29	1%
Red-tailed Hawk	551	14	3%	29	5%
Yellow-billed Cuckoo	42	14	33%	29	69%
Canada Lynx	10625	14	0%	29	0%
Grizzly Bear	32000	14	0%	29	0%
Long-tailed Weasel	12	14	117%	29	242%
Wolverine	26000	14	0%	29	0%

Thus, the concern for underestimation of exposure to higher concentrations reflected by the ISS results compared to the discrete samples is minor for the mourning dove, red-tailed hawk, Canada lynx, grizzly

bear, and wolverine, as the portion of their home range that is comprised of the ISS grid for their particular exposure areas is negligible. Concern is greater for the American woodcock and long-tailed weasel, both of which have home range sizes smaller than the area covered by the ISS grid in both exposure areas. The home range of the yellow-billed cuckoo substantially overlaps (33 and 69 percent) the ISS sampling grid in both exposure areas, as well.

This evaluation assumes that medium- and large-ranged receptors utilize a foraging area equal to the size of their home range and centered in the Main Plant or Central Landfills Area. The underestimation of risk may be greater for any receptors whose home ranges are centered on the Operational Area (rather than centered on the Main Plant Area or Central Landfills Area, for example). However, the Operational Area is one of the most industrially developed and disturbed areas of the Site, and the infrastructure and associated habitat degradation attributable to historical activities in this portion of the Site have resulted in low quality ecological resources that would likely be avoided by wildlife foraging in the area. The American woodcock represents avian insectivores, and some members of this foraging guild (e.g., the American robin) are tolerant of human presence and development, but a vast majority of the species represented by the American woodcock (avian insectivore) and long-tailed weasel (mammalian carnivore) are unlikely to regularly occur in the Operational Area. The yellow-billed cuckoo is a threatened species that is evaluated for individual protection rather as a representative of a specific foraging guild, but the presence of yellow-billed cuckoo is unlikely due to its rarity in Montana and, even if present in the vicinity of the Site, the usable habitat for the yellow-billed cuckoo is lacking in the Operational Area (see **Section 6.1.1.3** for additional discussion on the habitat requirements for this sensitive species). Therefore, the low likelihood for populations of larger ranging receptors to forage exclusively within the Operational Area is a moderating consideration for this portion of the Site.

The evaluation of the ISS samples on a point-by-point basis for small range receptors (i.e., the meadow vole and short-tailed shrew) reduces concern that ecological risks associated with exposure to the Operational Area are being underestimated, as these receptors typically are protective of larger ranging receptors owing to their small body size (toxicity and body size are generally inversely related because smaller sized animals need to consume more food relative to their body weight than larger animals) and localized exposure ranges. Larger range receptors typically occupy higher trophic order niches in the food chain and are therefore important to consider with regards to potential effects associated with bioaccumulation in the food chain. However, most metals and PAHs in terrestrial systems have relatively low bioaccumulation potential. Therefore, although risk associated with the constituents exhibiting higher concentrations in the ISS samples may be underestimated for larger-range receptors that incorporate part or all of the Operational Area into their home range, it is unlikely that the BERA conclusions are affected by this finding, and the list of constituents that potentially result in unacceptable risk using the point-by-point evaluation for small range receptors are most likely protective of larger-ranging receptors as well.

8 BERA Summary and Conclusions

The findings of the BERA are summarized to clearly identify the assessment procedures used, the potential risks identified, and the uncertainties associated with the conclusions. The BERA findings are evaluated for each ecological exposure area to support area-specific recommendations to guide risk management decision-making for the Site.

8.1 Terrestrial Exposure Areas

The overall results of the BERA for the terrestrial exposure areas are presented in **Table 8-1** and are summarized in this section.

8.1.1 Main Plant Area

Risk estimates for the Main Plant Area—particularly in the north-central portion of this exposure area--indicate the potential for adverse effects associated with exposure to PAHs in soil within localized portions of the Main Plant Area that are proximal to former operations. Direct contact exposure to PAHs in the Main Plant Area may potentially result in adverse effects to terrestrial invertebrates in these localized areas. PAHs were also responsible for two avian receptors (the American woodcock and yellow-billed cuckoo) having wildlife ingestion HQ_{LOAEL} values that exceeded 1, primarily due to the modeled ingestion of terrestrial invertebrates.

Based on these findings, the potential for ecological receptors to be adversely affected by constituents in soil in the Main Plant Area cannot be entirely dismissed under current conditions. However, concern regarding COPECs in the Main Plant Area is reduced because of the poor habitat available under current, developed conditions. Further evaluation of exposure to soils with elevated concentrations in the identified localized areas may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.

8.1.2 Central Landfills Area

Risk estimates for the Central Landfills Area indicate the limited potential for adverse effects associated with direct contact to soil constituents. The direct contact risk evaluation performed at the Central Landfills exposure area indicates that potential risk to soil invertebrates and terrestrial plants is low, although localized areas of PAHs and one elevated copper result at CFSB-002 (7,260 mg/kg) resulted in some NOEC and LOEC exceedances. This sample had concentrations of copper that were an order of magnitude greater than the next highest detected concentration and two orders of magnitude greater than the mean in this exposure area. Therefore, this sample is considered anomalous, and the EPCs that were highly influenced by this anomalous sample resulted in risk estimates that far exceed what would be considered representative for the site as a whole. Wildlife ingestion models indicate the potential for adverse effects associated with exposure to copper, PAHs, and Aroclor 1254 assuming conservative exposure assumptions. The modeled ingestion of terrestrial invertebrate prey items was the critical exposure pathway for all COPECs and receptors. Similar to the direct contact pathways, EPCs for copper are driven by an anomalously high concentration at a single station. An EPC for copper calculated with the anomalous concentration excluded resulted in negligible risks for wildlife receptors. EPCs for PAHs were also influenced by localized stations with elevated concentrations. The small range receptor evaluation indicated several sample locations (e.g., CFLP-009, CFSB-004, CFLP-012, CFSB-227, CFSB-224)

with concentrations exceeding the LOAEL-based soil benchmarks for the short-tailed shrew in the area where the Wet Scrubber Sludge Pond was formerly located and in the southern portion of the exposure area between the Wet Scrubber Sludge Pond and the Main Plant Area.

Based on these findings, the potential for ecological receptors to be adversely affected by constituents in soil in the Central Landfills Area cannot be entirely dismissed under current conditions. However, concern regarding COPECs in the Central Landfills Area is reduced because of the poor habitat available under current, developed conditions. Further evaluation of exposure to soils with elevated concentrations in the identified localized areas may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.

8.1.3 Incremental Soil Sampling Grid

Risk estimates for the ISS Grid were similar to risk estimates for overlapping areas within the Main Plant Area and Central Landfills Area. Direct contact resulted in moderate risk to soil invertebrates and plants based on contact with PAHs and select metals, including copper, selenium (plants only) and zinc. Several of the DUs, particularly in the central third of the ISS Grid within the Central Landfills Area, had concentrations of constituents that exceeded LOAEL-based benchmarks protective of small range receptors. Exceedances of LOAEL-based benchmarks in these DUs were primarily associated with LMW and HMW PAH exposure to short-tailed shrew.

Based on these findings, the potential for ecological receptors to be adversely affected by constituents in soil in some ISS grids cannot be entirely dismissed under current conditions. However, concern regarding COPECs in the Operational Area where the ISS grids were located is reduced because of the poor habitat available under current, developed conditions. Further evaluation of exposure to soils with elevated concentrations in the identified localized areas may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.

8.1.4 Industrial Landfill Area

Risk estimates for the Industrial Landfill Area indicate minimal potential for adverse effects associated with exposure to constituents in soil. The results of the food chain model indicated that nickel (American woodcock and short-tailed shrew) and HMW PAHs (American woodcock and yellow-billed cuckoo) had HQ_{LOAEL} values that exceeded 1 in this exposure area, primarily due to the modeled ingestion of terrestrial invertebrate prey items. All HQ_{LOAEL} values were less than 5, however. Therefore, nickel and PAHs in soil at the Industrial Landfills Area represent a moderate risk to ecological receptors due to exposure from direct and indirect ingestion pathways.

Based on these findings, the potential for ecological receptors to be adversely affected by constituents in soil in the Industrial Landfill Area cannot be entirely dismissed under current conditions. However, concern regarding COPECs in the Industrial Landfill Area is reduced because of the poor habitat available under current, developed conditions. Further evaluation of exposure to soils with elevated concentrations in the identified localized areas may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.

8.1.5 Eastern Undeveloped Area

Risk estimates for the Eastern Undeveloped Area indicate negligible potential for adverse effects associated with exposure to soil. No further evaluation to assess the potential for ecological risk is warranted in this exposure area.

8.1.6 North-Central Undeveloped Area

Risk estimates for the North-Central Undeveloped Area indicate negligible potential for adverse effects associated with exposure to soil. No further evaluation to assess the potential for ecological risk is warranted in this exposure area.

8.1.7 Western Undeveloped Area

Risk estimates for the Western Undeveloped Area indicate negligible potential for adverse effects associated with exposure to soil. No further evaluation to assess the potential for ecological risk is warranted in this exposure area.

8.1.8 Flathead River Riparian Area

Risk estimates for the Flathead River Riparian Area indicate negligible potential for adverse effects associated with exposure to soil. No further evaluation to assess the potential for ecological risk is warranted in this exposure area.

8.2 Transitional Exposure Areas

The overall results of the BERA for the transitional exposure areas are presented in **Table 8-2** (terrestrial evaluation) and **Table 8-3** (aquatic evaluation) and are summarized in this section.

8.2.1 North Percolation Pond Area

Elevated risks associated with direct contact to aquatic and terrestrial plants and invertebrates, and to multiple wildlife receptors foraging on benthic and terrestrial invertebrates were present in the North Percolation Ponds. Concentrations were present in every soil sample that exceeded the LOAEL benchmark protective of small-range receptors. Cyanide and several metals (e.g., barium, nickel, selenium, and vanadium) and PAHs were responsible for this elevated risk. The greatest potential for adverse effects was attributable to the North-East Percolation Pond.

Further actions should be considered to reduce or further study the elevated ecological risk at this exposure area. Further risk assessment may not be beneficial, particularly in the North-East Pond until the future uses of the North Percolation Pond are determined.

8.2.2 South Percolation Pond Area

The potential for adverse effects associated with constituents in media at the South Percolation Pond Area is considered minimal under dry scenarios, but moderate under inundated scenarios due to

potential adverse effects associated with direct contact with cyanide, metals, and PAHs in surface water. One potential action that could address this elevated risk is to evaluate the potential for minimizing stormwater discharge with elevated concentrations of cyanide, aluminum, and other COPECs to the South Percolation Ponds.

8.2.3 Cedar Creek Reservoir Overflow Ditch

The potential for adverse effects associated with constituents in media at the Cedar Creek Reservoir Overflow Ditch Area is considered minimal under both dry and inundated scenarios. No further evaluation to assess the potential for ecological risk is warranted in this exposure area.

8.2.4 Northern Surface Water Feature

The potential for adverse effects associated with constituents in media at the Northern Surface Water Feature Area is considered minimal under both dry and inundated scenarios. No further evaluation to assess the potential for ecological risk is warranted in this exposure area.

8.3 Aquatic Exposure Areas

The overall results of the BERA for the aquatic exposure areas are presented in **Table 8-4** and are summarized in this section.

8.3.1 Flathead River

Elevated risk associated with direct contact to aquatic receptors was noted within the Backwater Seep Sampling Area/Flathead River Riparian Channel, and was greatest for cyanide, barium, and aluminum in surface water and pore water. Ecological risk associated with direct contact within this limited area was considered moderate. However, rapid attenuation with increasing distance from the seep area was noted, and the potential for ecological risk in the main channel of the Flathead River for both direct contact and wildlife ingestion pathways was considered minimal and negligible, respectively. Further evaluation of chronic, direct contact exposure to cyanide in surface water and pore water in the Backwater Seep Sampling Area/Flathead River Riparian Channel may be warranted.

8.3.2 Cedar Creek

Potential risks associated with direct contact with surface water and sediment in Cedar Creek are negligible. No further evaluation to assess the potential for ecological risk is warranted in this exposure area.

Tables

Table 3-1
Qualitative Assessment of Habitat Use by Representative Receptors
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Exposure Area	Habitat Description[1]	Habitat Use Ranks[2,3]								
		American Dipper	American Woodcock	Belted Kingfisher	Mourning Dove	Yellow-Billed Cuckoo	Canada Lynx	Grizzly Bear	Meadow Vole	Short-tailed Shrew
Terrestrial Exposure Areas										
Main Plant Area (231.9 acres)	Limited habitat quality due to former plant operations; characterized by early successional, non-woody vegetation and compacted soil; infrastructure related to former operations.	NA	1*	NA	3	1	1	1	4	3
Central Landfills Area (44.4 acres)	Limited habitat quality due to former plant operations; characterized by early successional, non-woody vegetation and compacted soil. Highest quality habitat at eastern boundary of exposure area.	NA	1*	NA	3	1	1	1	4	3
Industrial Landfill Area (12.6 acres)	Inactive, uncapped landfill. Reduced habitat quality due to landfill maintenance; characterized by early successional, non-woody vegetation.	NA	2*	NA	4	1	2	2	4	3
Eastern Undeveloped Area (64.9 acres)	Mix montane mixed conifer forest and lower montane grassland; montane-foothill deciduous shrubland located to the northeast and east of the Main Plant Area. Used by multiple avian and mammalian terrestrial receptor guilds.	NA	3	NA	4	2	2	3	5	4
North-Central Undeveloped Area (114.4 acres)	Mix montane mixed conifer forest and lower montane grassland; used by multiple avian and mammalian terrestrial receptor guilds.	NA	3	NA	4	2	2	3	5	4
Western Undeveloped Area (439.6 acres)	Mix montane mixed conifer forest and lower montane grassland; riparian woodland habitat dominated by cottonwood (*Populus spp.*) borders Cedar Creek. Used by multiple avian and mammalian receptor guilds.	NA	3	NA	4	2	2	3	5	4
Flathead River Riparian Area (93.9 acres)	Riparian woodland habitat dominated by cottonwood (*Populus spp.*), boxelder (*Acer negundo*), quaking aspen (*Populus tremloides*), and paper birch (*Betula papyrifera*). Maintained utility corridor. Used by multiple terrestrial and semi-aquatic avian and mammalian receptor guilds.	NA	4	NA	4	2	2	3	5	5
Transitional Exposure Areas										
Cedar Creek Reservoir Overflow Ditch (5.2 acres)	Intermittent surface water conveyance controlled by surface water discharge from the Cedar Creek Reservoir.	1	1*	1	2	1	1	1	1	1
South Percolation Pond Area (5.6 acres)	Three interconnected former process ponds located adjacent to the Flathead River; currently only stormwater discharges to the ponds. Variable hydrology from complete inundation during wet season to limited inundation during the dry season. Potential seasonal habitat for amphibians and tolerant invertebrates.	1*	2*	3	3	1	1	2	2	2
Northern Surface Water Feature (6.1 acres)	Seasonally and interannually variable surface water feature fed by groundwater discharge; potential temporary habitat for amphibians and tolerant invertebrates.	1*	3	2	3	2	2	3	4	4
North Percolation Pond Area (11.3 acres)	Two interconnected former process ponds; currently receives stormwater discharge. Variable hydrology related to stormwater discharge; not inundated during the dry season. Potential seasonal habitat for amphibians and tolerant invertebrates.	1*	1*	1	2	1	1	1	2	2
Aquatic Exposure Areas										
Flathead River	Coldwater river that supports the growth and propagation of salmonid fishes and associate aquatic life; fisheries near the Site are fairly limited by sub-optimal stream channel habitat.	3	NA	4	NA	NA	NA	NA	NA	NA
Cedar Creek	Second order tributary to the Flathead River; coldwater habitat that likely supports fish, however, small channel size limits biomass of edible sized fish.	4	NA	5	NA	NA	NA	NA	NA	NA

Notes:

1, Habitat descriptions summarized based on the habitat assessment reported in the *Screening Level Ecological Risk Assessment* (Roux, 2017b).

2, Habitat Use Ranks:

1. Little to no habitat available at the exposure area for the receptor or surrogates; regular exposure to populations (or individual organisms, for sensitive species) highly unlikely.
2. Low quality habitat for the species is available in portions of the site, but regular exposure to populations (or individual organisms, for sensitive species) is not be expected. Low probability for receptor to be present regionally.
3. Habitat quality is moderate for receptor. Regular exposure to receptor at the site is possible, but risk estimates based on 100 percent exposure are likely overestimated.
4. Significant portions of the exposure area have habitat qualities favored by the receptor; the assumption that the receptor could be exposed to a majority of the site area is reasonable.
5. Habitat is ideal (or nearly ideal) for the species.

NA, Habitat is not applicable for the listed receptor.

3, An asterisk (*) indicates that although it is highly unlikely that the receptor species in question would use the site, other species in its foraging guild that it represents may utilize the area to some extent.

Receptor	Habitat Requirements
American Dipper:	Prefers fast-moving, clear streams along with waterfalls. Species prefers sand, pebble, or rocky stream bottoms, which provide sufficient aquatic invertebrates. Shorelines with large boulders, fallen trees, and rubble provide shelter and protection from predators (1.).
American Woodcock:	The woodcock is primarily found in the eastern U.S. There has only been a single record in the Montana in the past 10 years (1.). Hides in forest thickets by day, where it uses its long bill to probe in damp soil for earthworms (2.).
Belted Kingfisher:	Inhabits streams, rivers, ponds, lakes, and estuaries or calm marine waters in which prey are clearly visible. Availability of suitable nesting sites - earthen banks where nesting burrows can be excavated - appears critical for the distribution and local abundance of this species (1.).
Mourning Dove:	Species has tremendous adaptability. Generally shuns deep woods or extensive forest and selects more open woodlands and edges between forest and prairie biomes for nesting. Human alteration of original vegetations is generally beneficial for this species (1.).
Yellow-Billed Cuckoo:	Rarely observed in Montana. Requires dense, wooded habitats with cover and water nearby, particularly cottonwood-dominated forests canopies (Hughes, 2015; MNHP, 2019). Western subspecies require patches of at least 10 hectares (25 acres) of dense, riparian forest with a canopy cover of at least 50 percent in both the understory and overstory. The Yellow-billed Cuckoo is known in Montana only in June and July. All of these observations indicate no behavioral evidence to suggest breeding (1.).
Canada Lynx:	Moist, boreal spruce-fir forest habitat, particularly dense stands of young conifers. In northwestern Montana, primary vegetation may include cedar-hemlock habitat types (1.).
Grizzly Bear:	Relatively undisturbed mountainous habitat ranging from dense forest to subalpine meadows. In Montana, primarily meadows, seeps, riparian zones, mixed shrub fields, open timber, closed timber. Habitat use is highly variable between areas and seasons (1.).
Meadow Vole:	Wet grassland habitat but not above timberline in grassy alpine tundra. *M. pennsylvanicus* may inhabit drier grasslands than *M. montanus* (1.).
Short-tailed Shrew:	Most common in hardwood forests with deep leaf litter and in brushy sites adjacent to ponds and streams, less common in conifer forest and grassland (1.).

Notes:

Table 4-2
Samples Used in the Baseline Ecological Risk Assessment - Central Landfills Area
Central Landfills Area Terrestrial Exposure Area
Columbia Falls Aluminum Company
Columbia Falls, Montana

Location	Sample Number	Sample Date	Depth (ft)	Analyses

[a]: Triplicate incremental field replicates were collected for these samples.

Gen Chem: general chemistry parameters

Hex Chrom: hexavalent chromium

PCBs: polychlorinated biphenyls

Pest: pesticides

Phys: physical characteristics

SVOCs: semivolatile organic compounds

VOCs: volatile organic compounds

Notes:

[a]: Samples collected from channel draining the Flathead River Riparian Area to the Backwater Seep Sampling Area. Although located in the Flathead River Riparian Area, these samples will collected primarily to evaluate cyanide and fluoride pathways from the shallow groundwater to the Backwater Seep area, and will be evaluated separately.

Gen Chem: general chemistry parameters

Metals-SEM: simultaneously extracted metals

Metals (f&uf): filtered and unfiltered metals

PCBs: polychlorinated biphenyls

Pest: pesticides

SVOCs: semivolatile organic compounds

SVOCs-SIM: semivolatile organic compounds, selected ion monitoring

VOC: volatile organic compounds

Reference Area Selection for Ecological Exposure Areas
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Exposure Areas	Predominant Soil Type	Secondary Soil Type	Contribution of Secondary Soil Type	Soil Reference Area for Comparison	Notes	Sediment Reference Area for Comparison	Notes	Surface Water Reference Area for Comparison	Notes
Terrestrial Exposure Areas									
Main Plant Area	Qgr; Glacial and Fluvioglacial Deposits (Pleistocene)	None	NA	SO 1 (Glacial Till and Alluvium)		NA		NA	
Central Landfills Area	Qgr; Glacial and Fluvioglacial Deposits (Pleistocene)	Yr; Revett Formation (Middle Proterozoic) (Teakettle Mountain)	Minor	SO 1 (Glacial Till and Alluvium)		NA		NA	
Industrial Landfill Area	Qgr; Glacial and Fluvioglacial Deposits (Pleistocene)	None	NA	SO 1 (Glacial Till and Alluvium)		NA		NA	
Eastern Undeveloped Area	Qgr; Glacial and Fluvioglacial Deposits (Pleistocene)	Yr; Revett Formation (Middle Proterozoic) (Teakettle Mountain)	Minor	SO 1 (Glacial Till and Alluvium)		NA		NA	
North-Central Undeveloped Area	Qgr; Glacial and Fluvioglacial Deposits (Pleistocene)	Yr; Revett Formation (Middle Proterozoic) (Teakettle Mountain)	Minor	SO 1 (Glacial Till and Alluvium)		NA		NA	
Western Undeveloped Area	Qgr; Glacial and Fluvioglacial Deposits (Pleistocene)	Qgl; Glacial Lake Deposit	Very Minor	SO 1 (Glacial Till and Alluvium)		NA		NA	
Flathead River Riparian Area	Qal; Alluvial Deposits (Holocene)	None	NA	Lower of SO 2 and SO 3 (Fluvial Deposits and Riverwash)	1.	NA		NA	
Transitional Exposure Areas									
North Percolation Pond Area	Qgr; Glacial and Fluvioglacial Deposits (Pleistocene)	None	NA	SO 1 (Glacial Till and Alluvium)		SO 1 (Glacial Till and Alluvium)	2.	Cedar Creek	3.
Cedar Creek Reservoir Overflow Ditch	Qgr; Glacial and Fluvioglacial Deposits (Pleistocene)	None	NA	SO 1 (Glacial Till and Alluvium)		Cedar Creek		Cedar Creek	3.
South Percolation Pond Area	Qal; Alluvial Deposits (Holocene)	None	NA	Lower of SO 2 and SO 3 (Fluvial Deposits and Riverwash)	1.	Lower of SO 2 and SO 3 (Fluvial Deposits and Riverwash)	1., 2.	Flathead River	3.
Northern Surface Water Feature	Qgr; Glacial and Fluvioglacial Deposits (Pleistocene)	None	NA	SO 1 (Glacial Till and Alluvium)		SO 1 (Glacial Till and Alluvium)	2.	Cedar Creek	3.
Aquatic Exposure Areas									
Flathead River	NA					Flathead River		Flathead River	
Cedar Creek	NA					Cedar Creek		Cedar Creek	
Backwater Seeps Area (Flathead River Riparian Area)									
Seeps Area	NA					Flathead River		Flathead River	

NA, not applicable

Notes:

1. Soil type at Exposure Area similar to two Reference Areas; comparison will be made to the lower (more conservative) concentration from Reference Areas SO2 and SO3.
2. Depositional sediment at these transitional areas likely more similar to surrounding soil; therefore, comparison will be made to the corresponding soil Reference Area data for site sediment.
3. Reference Area water body selected based on proximity and drainage patterns at the Site.

Qal, alluvial deposits (soils deposited by Holocene)
Qgl, glacial lake deposit (Pleistocene)
Qgr, glacial and fluvioglacial deposits (pleistocenne)
Yr, Revett formation (middle Proterozoic)

Cedar Creek (All Media): NONE											

Notes:
µg/L: microgram per liter
BTV: Background threshold value
ESV: Ecological screening value
mg/kg: milligram per kilogram
NA: Not applicable; BTV and ESV values not available.
ND: No background data/ESV available
PAH: Polycyclic Aromatic Hydrocarbons
PCB: Polychlorinated Biphenyls
SVOC: Semi-Volatile Organic Compounds
TAL: Target Analyte List
TCL: Target Compound List
VOC: Volatile Organic Compounds

Basis for excluding for further evaluation:
A: Detected concentrations do not exceed criteria (i.e., maximum concentration is lower than the greater of 10-times the BTV and ESV).
B: Total PCBs data are identical to PCB-1254 (Aroclor 1254) data, which were not retained for further evaluation.
C: Neither ESVs nor BTVs are available; therefore, there is no basis to retain chemical.
D: Only one sample was detected or one result exceeds criteria; therefore, multiple samples representing a hot spot are not present.

Table 5-1
Summary of Ecological Receptors, Assessment Endpoints, Measurement Endpoints, and Risk Questions - Terrestrial Exposure Areas
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Ecological Receptor Category	Assessment Endpoints	Risk Questions	Focal Species/Level of Organization	Measurement Endpoints
Terrestrial Exposure Areas				
Soil Invertebrate Community	Survival, growth, and reproduction of amphibian populations to support the maintenance of viable and functional amphibian communities.	Are concentrations of site-related COPECs in surface water and sediment greater than effects thresholds for the survival, growth, or reproduction of amphibians?	Community	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative amphibian test organisms. 2) Comparisons of COPEC concentrations in sediment to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative amphibian test organisms.
Terrestrial Plant Community	Survival, growth, and reproduction of terrestrial plant populations to support the maintenance of viable and functional terrestrial plant communities.	Are concentrations of site-related COPECs in soil greater than effects thresholds for the survival, growth, or reproduction of terrestrial plants?	Community	1) Comparisons of COPEC concentrations in surficial soil (0-2-feet bgs) to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative terrestrial plants.
Special Status Species Terrestrial Plant	Survival, growth, and reproduction of Spalding's Catchfly (*Silene spaldingii*) individuals, if present, to support the maintenance of viable and functional populations.	Are concentrations of site-related COPECs in soil greater than effects thresholds for the survival, growth, or reproduction of terrestrial plants?	Individual - Threatened	1) Comparisons of COPEC concentrations in surficial soil (0-2-feet bgs) to NOECs derived from survival, growth, and reproductive endpoints for representative terrestrial plants.
Reptiles	Survival, growth, and reproduction of reptile populations to support the maintenance of viable and functional reptilian communities.	Are concentrations of site-related COPECs in surface water and sediment greater than effects thresholds for the survival, growth, or reproduction of reptiles?	Community	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative reptilian test organisms. 2) Comparisons of COPEC concentrations in sediment to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative reptilian test organisms.
Birds				
Carnivores	Survival, growth, and reproduction of avian carnivore populations to support the maintenance of viable and functional avian communities.	Does the daily dose of site-related COPEC experienced by carnivorous birds through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	Red-tailed hawk (Buteo jamaicensis)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Invertivores	Survival, growth, and reproduction of avian invertivore populations to support the maintenance of viable and functional avian communities.	Does the daily dose of site-related COPEC experienced by invertivorous birds through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	American woodcock (*Scolopax minor*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Herbivores	Survival, growth, and reproduction of avian herbivore populations to support the maintenance of viable and functional avian communities.	Does the daily dose of site-related COPEC experienced by herbivorous birds through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	Mourning dove (*Zenaida macroura*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Invertivores (Special Status Species)	Survival, growth, and reproduction of Yellow-billed Cuckoo (*Coccyzus americanus*) individuals, if present, to support the maintenance of viable and functional populations.	Does the daily dose of site-related COPEC experienced by Yellow-billed Cuckoo (*Coccyzus americanus*) through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	Individual - Threatened Yellow-billed Cuckoo (*Coccyzus americanus*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.

Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Ecological Receptor Category	Assessment Endpoints	Risk Questions	Focal Species/Level of Organization	Measurement Endpoints
Mammals				
Carnivores	Survival, growth, and reproduction of mammalian carnivore populations to support the maintenance of viable and functional mammalian communities.	Does the daily dose of site-related COPEC experienced by carnivorous mammals through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Long-tailed weasel (*Mustela frenata*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Invertivores	Survival, growth, and reproduction of mammalian invertivore populations to support the maintenance of viable and functional mammalian communities.	Does the daily dose of site-related COPEC experienced by invertivorous mammals through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Northern short-tailed shrew (*Blarina brevicauda*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Herbivores	Survival, growth, and reproduction of mammalian herbivore populations to support the maintenance of viable and functional mammalian communities.	Does the daily dose of site-related COPEC experienced by herbivorous mammals through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Meadow vole (Microtus pennsylvanicus)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Carnivores (Special Status Species)	Survival, growth, and reproduction of Canada Lynx (*Lynx canadensis*) individuals, if present, to support the maintenance of viable and functional populations.	Does the daily dose of site-related COPEC potentially experienced by Canada Lynx through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Individual - Threatened Canada Lynx (*Lynx canadensis*)	Comparison of NOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Carnivores (Special Status Species)	Survival, growth, and reproduction of Grizzly Bear (*Ursus arctos horribilis*) individuals, if present, to support the maintenance of viable and functional populations.	Does the daily dose of site-related COPEC potentially experienced by Grizzly Bear through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Individual - Threatened Grizzly Bear (*Ursus arctos horribilis*)	Comparison of NOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Carnivores (Special Status Species)	Survival, growth, and reproduction of North American Wolverine (*Gulo gulo luscus*) individuals, if present, to support the maintenance of viable and functional populations.	Does the daily dose of site-related COPEC potentially experienced by North American Wolverine through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Individual - Proposed Threatened North American Wolverine (*Gulo gulo luscus*)	Comparison of NOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.

Ecological Receptor Category	Assessment Endpoints	Risk Questions	Focal Species/Level of Organization	Measurement Endpoints
Transitional Exposure Areas				
Benthic invertebrate community	Survival, growth, and reproduction of benthic macroinvertebrate populations to support the maintenance of viable and functional benthic macroinvertebrate communities.	Are concentrations of site-related COPECs in sediment, pore water, or surface water greater than effects thresholds for the survival, growth, or reproduction of benthic invertebrates?	Population	Tier 1: 1) Comparisons of COPEC concentrations in bulk sediment to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative benthic invertebrate test organisms. 2) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative benthic invertebrate test organisms. Tier 2: 3) Comparisons of COPEC concentrations in pore water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative benthic invertebrate test organisms.
		Is the survival or growth of freshwater test organisms exposed to whole sediments from transitional exposure areas significantly lower than comparable endpoints for test organisms exposed to whole sediments from reference areas?	Population	Tier 3: 4) SQT Line of Evidence: Sediment Toxicity Testing Statistical comparisons of survival, growth, and biomass endpoints from chronic, long-term sediment toxicity testing of bulk sediments from aquatic exposure areas to comparable endpoints from reference areas.
		Is the benthic community structure in transitional exposure areas different from the benthic community structure in reference areas with similar habitat? If differences in structure are observed, are those differences explained by site-related COPEC concentrations in abiotic exposure media and/or other habitat parameters?	Community	5) SQT Line of Evidence: Benthic Invertebrate Community Analysis a) SQT Line of Evidence: Statistical comparisons of multiple metrics (e.g., richness, composition, tolerance measures) that measure the structure and function of benthic invertebrate communities between study and reference stations; statistical evaluation of the results of the multi-metric community analyses with site-related COPEC concentrations in exposure media and other habitat parameters. b) Multivariate statistical comparisons (e.g., ordination) of benthic invertebrate taxa-abundance data to evaluate the structure and function of benthic communities between exposure area and reference area stations.
Soil invertebrate community	Survival, growth, and reproduction of amphibian populations to support the maintenance of viable and functional amphibian communities.	Are concentrations of site-related COPECs in surface water and sediment greater than effects thresholds for the survival, growth, or reproduction of amphibians?	Population	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative amphibian test organisms. 2) Comparisons of COPEC concentrations in sediment to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative amphibian test organisms.
Aquatic plant community	Survival, growth, and reproduction of aquatic plant populations to support the maintenance of viable and functional aquatic plant communities.	Are concentrations of site-related COPECs in surface water greater than effects thresholds for the survival, growth, or reproduction of aquatic plants?	Population	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative aquatic plant test organisms.

Ecological Receptor Category	Assessment Endpoints	Risk Questions	Focal Species/Level of Organization	Measurement Endpoints
Terrestrial plant community	Survival, growth, and reproduction of terrestrial plant populations to support the maintenance of viable and functional terrestrial plant communities.	Are concentrations of site-related COPECs in soil greater than effects thresholds for the survival, growth, or reproduction of terrestrial plants?	Population	1) Comparisons of COPEC concentrations in surficial soil (0-2-feet bgs) to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative terrestrial plants.
Amphibians	Survival, growth, and reproduction of amphibian populations to support the maintenance of viable and functional amphibian communities.	Are concentrations of site-related COPECs in surface water and sediment greater than effects thresholds for the survival, growth, or reproduction of amphibians?	Population	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative amphibian test organisms. 2) Comparisons of COPEC concentrations in sediment to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative amphibian test organisms.
Reptiles	Survival, growth, and reproduction of reptile populations to support the maintenance of viable and functional reptilian communities.	Are concentrations of site-related COPECs in surface water and sediment greater than effects thresholds for the survival, growth, or reproduction of reptiles?	Population	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative reptilian test organisms. 2) Comparisons of COPEC concentrations in sediment to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative reptilian test organisms.
Birds				
Terrestrial carnivores	Survival, growth, and reproduction of avian carnivore populations to support the maintenance of viable and functional avian communities.	Does the daily dose of site-related COPEC experienced by carnivorous birds through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	Red-tailed hawk (Buteo jamaicensis)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Terrestrial invertivores	Survival, growth, and reproduction of avian invertivore populations to support the maintenance of viable and functional avian communities.	Does the daily dose of site-related COPEC experienced by invertivorous birds through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	American woodcock (*Scolopax minor*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Terrestrial herbivores	Survival, growth, and reproduction of avian herbivore populations to support the maintenance of viable and functional avian communities.	Does the daily dose of site-related COPEC experienced by herbivorous birds through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	Mourning dove (*Zenaida macroura*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Semi-Aquatic invertivore	Survival, growth, and reproduction of semi-aquatic avian invertivore populations to support the maintenance of viable and functional avian communities.	Does the daily dose of site-related COPEC experienced by semi-aquatic invertivorous birds through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	American dipper (*Cinclus mexicanus*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, sediment, and surface water.

Mammals				
Terrestrial carnivores	Survival, growth, and reproduction of mammalian carnivore populations to support the maintenance of viable and functional mammalian communities.	Does the daily dose of site-related COPEC experienced by carnivorous mammals through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Long-tailed weasel (*Mustela frenata*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Terrestrial invertivores	Survival, growth, and reproduction of mammalian invertivore populations to support the maintenance of viable and functional mammalian communities.	Does the daily dose of site-related COPEC experienced by invertivorous mammals through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Northern short-tailed shrew (*Blarina brevicauda*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Terrestrial herbivores	Survival, growth, and reproduction of mammalian herbivore populations to support the maintenance of viable and functional mammalian communities.	Does the daily dose of site-related COPEC experienced by herbivorous mammals through the direct ingestion of dietary items, incidental ingestion of soil/sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Meadow Vole (Microtus pennsylvanicus)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Carnivores (Special Status Species)	Survival, growth, and reproduction of Canada Lynx (*Lynx canadensis*) individuals, if present, to support the maintenance of viable and functional populations.	Does the daily dose of site-related COPEC potentially experienced by Canada Lynx through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Individual - Threatened Canada Lynx (*Lynx canadensis*)	Comparison of NOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Carnivores (Special Status Species)	Survival, growth, and reproduction of Grizzly Bear (*Ursus arctos horribilis*) individuals, if present, to support the maintenance of viable and functional populations.	Does the daily dose of site-related COPEC potentially experienced by Grizzly Bear through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Individual - Threatened Grizzly Bear (*Ursus arctos horribilis*)	Comparison of NOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.
Carnivores (Special Status Species)	Survival, growth, and reproduction of North American Wolverine (*Gulo gulo luscus*) individuals, if present, to support the maintenance of viable and functional populations.	Does the daily dose of site-related COPEC potentially experienced by North American Wolverine through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from transitional exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Individual - Proposed Threatened North American Wolverine (*Gulo gulo luscus*)	Comparison of NOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs in dietary items, soil, and surface water.

Aquatic Exposure Areas				
Benthic invertebrate community	Survival, growth, and reproduction of benthic macroinvertebrate populations to support the maintenance of viable and functional benthic macroinvertebrate communities.	Are concentrations of site-related COPECs in sediment, pore water, or surface water greater than effects thresholds for the survival, growth, or reproduction of benthic invertebrates?	Population	Tier 1: 1) Comparisons of COPEC concentrations in bulk sediment to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative benthic invertebrate test organisms. 2) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative benthic invertebrate test organisms. Tier 2: 3) Comparisons of COPEC concentrations in pore water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative benthic invertebrate test organisms.
		Is the survival or growth of freshwater test organisms exposed to whole sediments from aquatic exposure areas significantly lower than comparable endpoints for test organisms exposed to whole sediments from reference areas?	Population	Tier 3: 4) SQT Line of Evidence: Sediment Toxicity Testing Statistical comparisons of survival, growth, and biomass endpoints from chronic, long-term sediment toxicity testing of bulk sediments from aquatic exposure areas to comparable endpoints from reference areas.
		Is the benthic community structure in aquatic exposure areas different from the benthic community structure in reference areas with similar habitat? If differences in structure are observed, are those differences explained by site-related COPEC concentrations in abiotic exposure media and/or other habitat parameters?	Community	5) SQT Line of Evidence: Benthic Invertebrate Community Analysis a) SQT Line of Evidence: Statistical comparisons of multiple metrics (e.g., richness, composition, tolerance measures) that measure the structure and function of benthic invertebrate communities between study and reference stations; statistical evaluation of the results of the multi-metric community analyses with site-related COPEC concentrations in exposure media and other habitat parameters. b) Multivariate statistical comparisons (e.g., ordination) of benthic invertebrate taxa-abundance data to evaluate the structure and function of benthic communities between exposure area and reference area stations.
Pelagic (water-column) invertebrates	Survival, growth, and reproduction of pelagic invertebrate populations to support the maintenance of viable and functional pelagic invertebrate communities.	Are concentrations of site-related COPECs in surface water greater than effects thresholds for the survival, growth, or reproduction of pelagic invertebrates?	Population	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative pelagic invertebrate test organisms.
Aquatic plant community	Survival, growth, and reproduction of aquatic plant populations to support the maintenance of viable and functional aquatic plant communities.	Are concentrations of site-related COPECs in surface water greater than effects thresholds for the survival, growth, or reproduction of aquatic plants?	Population	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative aquatic plant test organisms. 2) Comparisons of COPEC concentrations in pore water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative aquatic plant test organisms.

Ecological Receptor Category	Assessment Endpoints	Risk Questions	Focal Species/Level of Organization	Measurement Endpoints
Fish	Survival, growth, and reproduction of fish populations to support the maintenance of viable and functional fish communities.	Are concentrations of site-related COPECs in surface water greater than effects thresholds for the survival, growth, or reproduction of fish?	Population	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative fish test organisms (DEQ-7 standards are used preferentially).
Special Status Fish (Flathead River Only)	Survival, growth, and reproduction of Bull Trout (*Salvelinus confluentus*) individuals, if present, to support the maintenance of viable and functional populations.	Are concentrations of site-related COPECs in surface water greater than effects thresholds for the survival, growth, or reproduction of Bull Trout?	Individual - Threatened	1) Comparisons of COPEC concentrations in surface water to NOECs derived from survival, growth, and reproductive endpoints for salmonids.
Amphibians	Survival, growth, and reproduction of amphibian populations to support the maintenance of viable and functional amphibian communities.	Are concentrations of site-related COPECs in surface water greater than effects thresholds for the survival, growth, or reproduction of amphibians?	Population	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative amphibian test organisms. 2) Comparisons of COPEC concentrations in pore water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative amphibian test organisms.
Reptiles	Survival, growth, and reproduction of reptile populations to support the maintenance of viable and functional reptilian communities.	Are concentrations of site-related COPECs in surface water and sediment greater than effects thresholds for the survival, growth, or reproduction of reptiles?	Population	1) Comparisons of COPEC concentrations in surface water to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative reptilian test organisms. 2) Comparisons of COPEC concentrations in sediment to NOECs and LOECs derived from survival, growth, and reproductive endpoints for representative reptilian test organisms.
Birds				
Piscivores	Survival, growth, and reproduction of semi-aquatic avian populations to support the maintenance of viable and functional avian communities.	Does the daily dose of site-related COPEC experienced by piscivorous birds through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from aquatic exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	Belted Kingfisher (*Megaceryle alcyon*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs fish tissues, sediment, and surface water.
Invertivore		Does the daily dose of site-related COPEC experienced by omnivorous birds through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from aquatic exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of avian test organisms?	American Dipper (*Cinclus mexicanus*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs fish tissues, sediment, and surface water.
Mammals				
Piscivores	Survival, growth, and reproduction of piscivorous mammalian populations to support the maintenance of viable and functional mammalian communities.	Does the daily dose of site-related COPEC experienced by piscivorous mammals through the direct ingestion of dietary items, incidental ingestion of sediment, and direct ingestion of surface water from aquatic exposure areas exceed toxicity reference values (TRVs) for the survival, growth, or reproduction of mammalian test organisms?	Mink (*Mustela vison*)	Comparison of NOAEL and LOAEL TRVs to dietary doses modeled using estimated concentrations of site-specific COPECs fish tissues, sediment, and surface water.

	North-Central Undeveloped Area	0	0	0	0	0	0	0	0	1	0	0	0	1
	Western Undeveloped Area	0	0	0	0	0	0	0	0	0	1	0	0	1
	Flathead River Riparian Area	0	0	0	0	0	0	0	0	0	0	1	0	1

Shaded cells indicate that the receptor species home range is smaller than the target ecological exposure, and the receptor was assumed to have 100 percent exposure to that exposure area. See text for details. Please note that although the long-tailed weasel's home range of 12 acres slightly exceeds the area of the North Percolation Pond Area (11.3 acres), it was assumed that 100 percent of the weasel's exposure is derived from that exposure area.

Area of Exposure Areas[a]:

Main Plant Area	231.9	acres	Industrial Landfill Area	12.6	acres
Cedar Creek Reservoir Overflow Ditch	5.2	acres	Eastern Undeveloped Area	64.9	acres
South Percolation Pond Area	5.6	acres	North-Central Undeveloped Area	114.4	acres
Northern Surface Water Feature	6.1	acres	Western Undeveloped Area	439.6	acres
North Percolation Pond Area	11.3	acres	Flathead River Riparian Area	93.9	acres
Central Landfills Area	44.4	acres			

a, Please note that the percent inclusion values were spatially calculated assuming the receptor was placed in the geometric center of the target exposure area. Therefore, a receptor whose home range is smaller than the target exposure area may have exposure to a mixture of adjacent exposure areas and less than 100 percent exposure to the target exposure area if the assumed circular home range from that midpoint location did not fully overlap the target area and intersected adjacent areas.

Notes:
Shaded cells indicate that all values were non-detect. Value is the maximum method detection limit for all reference samples.
All values are in milligrams per kilogram (mg/kg).
a, SO1 BTVs are used to represent soil and sediment background concentrations in all exposure areas except for the Flathead River Riparian Area and the South Percolation Pond Area.
The lower of SO2 and SO3 BTVs for each chemical are used to represent soil background concentrations in the Flathead River Riparian Area and the South Percolation Pond Area.
BTV, Background threshold value
HMW, High molecular weight
LMW, Low molecular weight
LOAEL, Lowest-observed adverse effect level
NA, Not applicable; background considerations only apply to metals and PAHs
NC, Soil benchmark was not calculated due to a lack of TRVs
NOAEL, No observed adverse effect level
mg/kg, milligrams per kilogram

Notes:
--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion model results are presented in Appendix H2.
Dark shaded cells for threatened or endangered species indicate that conclusions for that species are only based upon HQ_{NOAEL} values.
HQ, Hazard quotient
$HQ_{LOAEL,}$ Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.
$HQ_{NOAEL,}$ Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.
$NOEC_{Plants}$, No Observed Effect Concentration, plants
PAH, Polycyclic Aromatic Hydrocarbon
PCB, Polychlorinated Biphenyl
SVOC, Semi-Volatile Organic Compound
VOC, Volatile Organic Compound

Notes:
--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion model results are presented in Appendix H2.
Dark shaded cells for threatened or endangered species indicate that conclusions for that species are only based upon HQ_{NOAEL} values.
HMW, High molecular weight
HQ, Hazard quotient
HQ_{LOAEL}, Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.
HQ_{NOAEL}, Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.
LMW, Low molecular weight
$NOEC_{Plants}$, No Observed Effect Concentration, plants
PAH, Polycyclic Aromatic Hydrocarbon
PCB, Polychlorinated Biphenyl
SVOC, Semi-Volatile Organic Compound
VOC, Volatile Organic Compound

Table 6-20
Summary of Refined Wildlife Hazard Quotients for the North Percolation Pond Area
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:
--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion model results are presented in Appendix H2.
Dark shaded cells for threatened or endangered species indicate that conclusions for that species are only based upon HQ_{NOAEL} values.
HMW, High molecular weight
HQ, Hazard quotient
$HQ_{LOAEL,}$ Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.
$HQ_{NOAEL,}$ Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.
LMW, Low molecular weight
$NOEC_{Plants}$, No Observed Effect Concentration, plants
PAH, Polycyclic Aromatic Hydrocarbon
PCB, Polychlorinated Biphenyl
SVOC, Semi-Volatile Organic Compound
VOC, Volatile Organic Compound

Notes:
µg/L, micrograms per liter
Fraction: U, Unfiltered; F, Filtered
Bold, value exceeds benchmark concentration (greater than 1)
HQ, Hazard quotient
HQ_{LOEC}, Hazard Quotient based on LOEC value
HQ_{NOEC}, Hazard Quotient based on NOEC value
LOEC, Lowest observed effect concentration
NOEC, No observed effect concentration

Table 6-27
Summary of Refined Wildlife Hazard Quotients for the South Percolation Pond Area
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:
--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion model results are presented in Appendix H2.
Dark shaded cells for threatened or endangered species indicate that conclusions for that species are only based upon HQ_{NOAEL} values.
HMW, High molecular weight
HQ, Hazard quotient
$HQ_{LOAEL,}$ Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.
$HQ_{NOAEL,}$ Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.
LMW, Low molecular weight
$NOEC_{Plants}$, No Observed Effect Concentration, plants
PAH, Polycyclic Aromatic Hydrocarbon
PCB, Polychlorinated Biphenyl
SVOC, Semi-Volatile Organic Compound
VOC, Volatile Organic Compound

Table 6-32
Summary of Refined Wildlife Hazard Quotients for the Cedar Creek Reservoir Overflow Ditch
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:
--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion model results are presented in Appendix H2.
Dark shaded cells for threatened or endangered species indicate that conclusions for that species are only based upon HQ_{NOAEL} values.
HMW, High molecular weight
HQ, Hazard quotient
$HQ_{LOAEL,}$ Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.
$HQ_{NOAEL,}$ Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.
LMW, Low molecular weight
$NOEC_{Plants}$, No Observed Effect Concentration, plants
PAH, Polycyclic Aromatic Hydrocarbon
PCB, Polychlorinated Biphenyl
SVOC, Semi-Volatile Organic Compound
VOC, Volatile Organic Compound

Table 6-39
Summary of Refined Wildlife Hazard Quotients for the Northern Surface Water Feature
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:
--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion model results are presented in Appendix H2.
Dark shaded cells for threatened or endangered species indicate that conclusions for that species are only based upon HQ_{NOAEL} values.
HMW, High molecular weight
HQ, Hazard quotient
$HQ_{LOAEL,}$ Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.
$HQ_{NOAEL,}$ Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.
LMW, Low molecular weight
$NOEC_{Plants}$, No Observed Effect Concentration, plants
PAH, Polycyclic Aromatic Hydrocarbon
PCB, Polychlorinated Biphenyl
SVOC, Semi-Volatile Organic Compound
VOC, Volatile Organic Compound

Table 6-48
Summary of Refined Wildlife Hazard Quotients for the Flathead River
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:

--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion model results are presented in Appendix H2.
Dark shaded cells for threatened or endangered species indicate that conclusions for that species are only based upon HQ_{NOAEL} values.

HMW, High molecular weight
HQ, Hazard quotient
$HQ_{LOAEL,}$ Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.
$HQ_{NOAEL,}$ Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.
LMW, Low molecular weight
PAH, Polycyclic Aromatic Hydrocarbon
PCB, Polychlorinated Biphenyl
SVOC, Semi-Volatile Organic Compound
VOC, Volatile Organic Compound

Notes:
µg/L, micrograms per liter
Fraction: U, Unfiltered; F, Filtered
---, Value not applicable
Bold, value exceeds benchmark concentration (greater than 1)
EPC, Exposure point concentration
HQ, Hazard quotient
HQ_{LOEC}, Hazard Quotient based on LOEC value
HQ_{NOEC}, Hazard Quotient based on NOEC value
LOEC, Lowest observed effect concentration
$LOEC_{inverts}$, Lowest Observed Effect Concentration, invertebrates
$LOEC_{Plants}$, Lowest Observed Effect Concentration, plants
NOEC, No observed effect concentration
$NOEC_{inverts}$, No Observed Effect Concentration, invertebrates
$NOEC_{Plants}$, No Observed Effect Concentration, plants
UCL_{Mean}, Upper confidence limit of the mean concentration

Total Dioxins/Furans	--	--	--	--	--	--

Notes:

--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion m

HQ, Hazard quotient

HQ_{LOAEL}, Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.

HQ_{NOAEL}, Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.

PAH, Polycyclic Aromatic Hydrocarbon

PCB, Polychlorinated Biphenyl

SVOC, Semi-Volatile Organic Compound

VOC, Volatile Organic Compound

Table 6-57
Summary of Wildlife Hazard Quotients Calculated using Max EPC
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:
NE: Receptor was not evaluated for the exposure area
Blank: HQ <1 or not measured
HQ: Hazard Quotient
NOAEL: No Observed Adverse Effects Level
LOAEL: Lowest Observed Adverse Effects Level
I: HQ>1
Shaded cells indicate LOAEL results for endangered species, which are evaluated based on their NOAEL results only.

Table 6-58
Summary of Area-Weighted Wildlife Hazard Quotients Calculated using Refined EPCs
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:

--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion model results are presented in Appendix H2.
HMW, High molecular weight
HQ, Hazard quotient
$HQ_{LOAEL,}$ Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.
$HQ_{NOAEL,}$ Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.
LMW, Low molecular weight
LOAEL: Lowest Observed Adverse Effects Level
NE: Receptor was not evaluated for the exposure area
NOAEL: No Observed Adverse Effects Level
PAH, Polycyclic Aromatic Hydrocarbon
PCB, Polychlorinated Biphenyl
SVOC, Semi-Volatile Organic Compound
VOC, Volatile Organic Compound

Shading key:
= indicates LOAEL results for endangered species, which are evaluated based on their NOAEL results only.
= HQ greater than 1, less than 10
= HQ greater than 10, less than 100
= HQ greater than 100

Table 6-59
Summary of Area-UnWeighted Wildlife Hazard Quotients Calculated using Refined EPCs
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:

--, HQ is negligible. Chemical was either not a COPEC, or had minimal HQs (i.e., <1) for all relevant exposure areas. Full ingestion model results are presented in Appendix H2.
HMW, High molecular weight
HQ, Hazard quotient
$HQ_{LOAEL,}$ Hazard quotient calculated using the lowest-observable-adverse-effect toxicity reference value.
$HQ_{NOAEL,}$ Hazard quotient calculated using the no-observable-adverse-effect toxicity reference value.
LMW, Low molecular weight
LOAEL: Lowest Observed Adverse Effects Level
NE: Receptor was not evaluated for the exposure area
NOAEL: No Observed Adverse Effects Level
PAH, Polycyclic Aromatic Hydrocarbon
PCB, Polychlorinated Biphenyl
SVOC, Semi-Volatile Organic Compound
VOC, Volatile Organic Compound

Shading key:
= indicates LOAEL results for endangered species, which are evaluated based on their NOAEL results only.
= HQ greater than 1, less than 10
= HQ greater than 10, less than 100
= HQ greater than 100

Results of One-Way ANOVA Between Percent Effluent and Percent Survival
in WET Testing in the Backwater Seep Sampling Area
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Table 6-61a. Results of One-Way Analysis of Variance of the Effect of Percent Effluent on Test Organism Survival

Factor	Sum of Squares	DF	F Statistic	p-value
Daphnid (*Ceriodaphnia dubia*)				
Percent Effluent	721	5	7.38	***<0.001***
Residuals	1994	102	--	--
Fathead minnow (*Pimephales promelas*)				
Percent Effluent	19.4	5	0.57	0.72
Residuals	697	102	--	--

Notes:
Response variable was percent survival of the test organism
-- Not applicable
DF - Degrees of Freedom

Table 6-61b. P-values from post hoc Tukey's Honestly Signficant Difference Test of the Effect of Percent Effluent on *Ceriodaphnia dubia*

Percent Effluent	0 (Control)	6.25	12.5	25	50	100
0 (Control)	---					
6.25	1	---				
12.5	1	1	---			
25	1	1	1	---		
50	0.7	0.5	0.3	0.7	---	
100	***<0.001***	***<0.001***	***<0.001***	***<0.001***	***<0.05***	---

Notes:
P-values indicating significant differences in mean survival ($p<0.05$) are presented in bold italics.

Table 6-61c. Difference in Mean Survival Between Effect of Percent Effluent on *Ceriodaphnia dubia*

Percent Effluent	0 (Control)	6.25	12.5	25	50	100
0 (Control)	---					
6.25	-0.3	---

Notes:

Constituents shown are chemicals of potential ecological concern for the two exposure areas.

Discrete sample data are for grab soil samples that occur within the incremental sample decision units that overlap the specific exposure area.

Incremental sample data represent the 95 percent upper confidence limit of the mean for decision units where triplicate samples were collected, or the measured (i.e., unadjusted) concentration for decision units lacking replication.

Half the quantitation limit substituted for non-detected results.

Shaded/bolded results indicate the mean of the incremental samples was greater than the mean of the discrete samples.

---, Not applicable.

HMW, High molecular weight

LMW, Low molecular weight

MDL, Method detection limit

mg/kg, milligrams per kilogram

PAH, Polycyclic Aromatic Hydrocarbon

PCB, Polychlorinated Biphenyl

PCE, Tetrachloroethylene

SVOC, Semi-Volatile Organic Compound

TAL, Target Analyte List

TCL, Target Compound List

Table 8-1
Summary of BERA Findings - Terrestrial Exposure Areas
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Exposure Area	Direct Contact Exposure Summary			Wildlife Exposure Summary			Preliminary Conclusions and Recommendations
	Soil Invertebrates	Terrestrial Plant Community	Overall Direct Contact Risk	Birds	Mammals	Overall Wildlife Risk	
Main Plant Area	Minimal Risk. Localized risk to soil invertebrates due to PAH exposure. Maximum EPCs > NOECs for LMW PAHs (HQ_{NOEC}=19) and HMW PAHs (HQ_{NOEC}=35.7). LOECs not identified for LMW and HMW PAHs. Refined EPCs > NOEC for LMW PAHs (HQ_{LOEC}=2.2) and HMW PAHs (HQ_{LOEC}=4.3). Negligible risk to other COPECs (maximum exposure < LOEC)	Negligible risk; maximum exposure < LOEC.	**Minimal**	**Maximum scenario:** Moderate Risk. Potential for adverse effects to birds exposed to HMW PAHs (HQ_{LOAEL}=11.5 to 16.3) and BEHP (HQ_{LOAEL}=3.0 to 4.5) if foraging exclusively at maximum EPC. **Refined scenario:** Moderate Risk.Limited potential for adverse effects to brids exposed to HMW PAHs (HQ_{LOAEL}=1.4 to 2.0)	**Maximum scenario:** Low potential for adverse effects for mammals foraging exclusively within the exposure area; maximum short-tailed shrew exposure HMW PAHs exceeds LOAEL (HQ_{NOAEL}=2.9); all other COPEC/receptors HQ_{LOAEL}<1. **Refined scenario:** Negligible risk foraging exclusively within the exposure area; Refined HQ_{LOAEL}<1. **Small Ranging Receptors:** Potential for adverse effects greatest for small mammals in northern portion of Main Plant within the Operational Area footprint; short-tailed shrew exposure > LOAEL at 5 of 90 stations and meadow vole exposure > LOAEL at 9 of 90 stations.	**Moderate**	Local impacts to soil invertebrate communities due to direct contact possible but localized. Possible impacts to birds foraging on terrestrial invertebrates (earthworms) in exposure area. Localized impacts to small-range mammalian receptors possible. Ecological expsure pathways limited under current, developed conditions; however, further evaluation of exposure may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.
Central Landfills Area	Negligible risk; Maximum EPCs < LOEC, except for copper (HQ_{LOEC}=13.7). Maximum EPCs > NOECs for LMW PAHs (HQ_{NOEC}=33) and HMW PAHs (HQ_{NOEC}=27). LOECs not identified for LMW and HMW PAHs. Refined EPC for copper (HQ_{LOEC}=1.4). Refined EPCs > NOEC for LMW PAHs (HQ_{LOEC}=3.0) and HMW PAHs (HQ_{LOEC}=3.0).	Negligible risk; maximum exposure < LOEC, except for copper; refined exposure estimate indicates slight exceedance of copper LOEC (HQ_{LOEC}=1.5).	**Minimal**	**Maximum scenario:** Moderate Risk. Potential for adverse effects to birds exposed to copper, nickel, LMW PAHs, HMW PAHs, Aroclor 1254 and BEHP (HQ_{LOAEL}=1.3 to 17.0) if foraging exclusively at maximum EPC. **Refined scenario:** Moderate Risk. Potential for adverse effects to birds exposed to copper, HMW PAHs, and Aroclor 1254 (HQ_{LOAEL}=1.3 to 3.1) if foraging exclusively at refined EPC.	**Maximum scenario:** Negligible Risk. Low potential for adverse effects for mammals foraging exclusively within the exposure area; maximum short-tailed shrew exposure exceeds LOAEL for copper, nickel, PCB1254, HMW PAHs and meadow vole for selenium (HQ_{NOAEL}=1.6 to 5.7); all other COPEC/receptors HQ_{LOAEL}<1. **Refined scenario:** Negligible risk foraging exclusively within the exposure area; Refined HQ_{LOAEL}<1. **Small Ranging Receptors:** Minimal Risk. Potential for adverse effects greatest for small mammals in northern portion of Main Plant within the Operational Area footprint; short tailed shrew exposure > LOAEL at 6 of 67 stations and meadow vole exposure < LOAEL.	**Moderate**	Possible impacts to birds foraging on terrestrial invertebrates (earthworms) in exposure area. Localized impacts to small-range mammalian receptors possible. Ecological expsure pathways limited under current, disturbed conditions; however, further evaluation of exposure may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.
Industrial Landfill Area	Minimal Risk. Limited risk due to PAH exposure. Maximum EPCs < LOECs for metals; maximum EPCs > NOECs for LMW PAHs (HQ_{NOEC}=7.0) and HMW PAHs (HQ_{NOEC}=13.4); LOECs not identified for LMW and HMW PAHs. Refined EPCs < LOECs for metals; refined EPCs > NOECs for for LMW PAHs (HQ_{NOEC}=6.5) and HMW PAHs (HQ_{NOEC}=12.9).	Negligible risk. Maximum EPCs < LOEC, except for slight exceedances of nickel (HQ_{LOEC}=1.7) and vanadium (HQ_{LOEC}=2.1). Refined exposure estimate indicates slight exceedances of LOECs for nickel (HQ_{LOEC}=1.5) and vanadium (HQ_{LOEC}=1.9).	**Minimal**	**Maximum scenario:** Moderate Risk. Potential for adverse effects to birds exposed to nickel and HMW PAHs (HQ_{LOAEL}=1.3 to 5.2) if foraging at maximum exposure exclusively within the Industrial Landfill Area. **Refined scenario:** Moderate Risk. Limited potential for adverse effects to birds exposued to refined EPCs for nickel and HMW PAHs (HQ_{LOAEL}=2.1 to 5.0).	**Maximum scenario:** Moderate Risk. nickel, vanadium, and HMW PAHs had HQ_{NOAEL} and HQ_{LOAEL} values greater than 1. **Refined scenario:** Moderate Risk. Nickel has HQ_{LOAEL} value > 1, but below 5. **Small Ranging Receptors:** Moderate risk. Two of the 6 sample locations exceeded the LOAEL benchmarks for the short-tailed shrew (nickel and PAHs).	**Moderate**	Possible impacts to birds foraging on terrestrial invertebrates (earthworms) in exposure area. Localized impacts to small-range mammalian receptors possible. Ecological expsure pathways limited under current, disturbed conditions; however, further evaluation of exposure may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.

Table 8-1
Summary of BERA Findings - Terrestrial Exposure Areas
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company

Exposure Area	Direct Contact Exposure Summary			Wildlife Exposure Summary			Preliminary Conclusions and Recommendations
	Soil Invertebrates	Terrestrial Plant Community	Overall Direct Contact Risk	Birds	Mammals	Overall Wildlife Risk	
Eastern Undeveloped Area	Negligible risk; maximum exposure < LOEC.	Negligible risk. Maximum EPCs < LOEC, except for barium (HQ_{LOEC}=4.1) and manganese (HQ_{LOEC}=3.6). Refined EPCs slightly exceed LOECs for barium (HQ_{LOEC}=2.2) and manganese (HQ_{LOEC}=1.3). Manganese comparable to background.	**Negligible**	**Maximum scenario:** Negligible risk to birds foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1; maximum cyanide HQ_{NOAEL}=1.0-1.4 (lead, nickel, vanadium, zinc, cyanide, and bis(2-ethylhexyl)phthalate) **Refined scenario:** Negligible risk to birds foraging exclusively within the exposure area; Refined HQ_{LOAEL}<1; refined EPCs < NOAEL, except for BEHP expsoure to yellow-billed cuckoo (HQ_{NOAEL}=1.2).	**Maximum scenario:** Negligible risk foraging exclusively within the exposure area; maximum short tailed short-tailed shrew exposure to nickel (HQ_{NOAEL}=1.7); other COPEC/receptors HQ_{NOAEL}<1 **Refined scenario:** Negligible risk foraging exclusively within the exposure area; Refined HQ_{LOAEL}<1; refined EPCs < NOAEL, except for nickel exposure to short-tailed shrew (HQ_{NOAEL}=1.0). **Small Ranging Receptors:** Negligible risk; < NOAEL for meadow vole for all constituents at 21 of 22 stations and < NOAEL for short-tailed shrew at 10 of 21 stations (max nickel HQ_{NOAEL}=1.7; HQ_{LOAEL} <1 for all other COPEC/receptors	**Negligible**	No further evaluation on the basis of terrestrial exposure.
North-Central Undeveloped Area	Negligible risk; maximum exposure < LOEC.	Negligible risk; Maximum EPCs < LOEC, except for barium (HQ_{LOEC}=1.9) and manganese (HQLOEC=2.4). Refined EPCs slightly exceed LOECs for barium (HQ_{LOEC}=1.1) and manganese (HQ_{LOEC}=1.0). Manganese comparable to background.	**Negligible**	**Maximum scenario:** Negligible risk to birds foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1; maximum cyanide HQ_{NOAEL}=1.2 to 1.5 and bis(2-ethylhexyl)phthalate (HQ_{NOAEL}=3.5 to 5.2). **Refined scenario:** Negligible risk to birds foraging exclusively within the exposure area; Refined HQ_{NOAEL}<1 .	**Maximum scenario:** Negligible risk to mammals foraging exclusively within the exposure area; maximum HQ_{NOAEL} <1 for all receptors/COPECs. **Refined scenario:** Negligible risk to mammals foraging exclusively within the exposure area; Refined HQ_{NOAEL}<1. **Small Ranging Receptors:** Negligible risk; < NOAEL for all stations for meadow vole and short-tailed shrew for refined COPECs.	**Negligible**	No further evaluation on the basis of terrestrial exposure.
Western Undeveloped Area	Negligible risk; maximum exposure < LOEC.	Negligible risk. Maximum EPCs < LOEC, except for barium (HQ_{LOEC}=2.1) and manganese (HQ_{LOEC}=2.0). Refined EPCs < LOEC, except for slight exceedance for barium (HQ_{LOEC}=1.2).	**Negligible**	**Maximum scenario:** Negligible risk to birds foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1; maximum HQ_{NOAEL}=1.2 to 2.7. **Refined scenario:** Negligible risk to birds foraging exclusively within the exposure area; Refined HQ_{NOAEL}<1.	**Maximum scenario:** Negligible risk to mammals foraging exclusively within the exposure area; maximum HQ_{NOAEL}=1.3 for short-tailed shrew $TEC_{2,3,7,8\text{-TCDD}}$; all other COPEC/receptors HQ_{NOAEL}<1. **Refined scenario:** Negligible risk to mammals foraging exclusively within the exposure area; maximum HQ_{NOAEL}=1.1 for short-tailed shrew $TEC_{2,3,7,8\text{-TCDD}}$; all other COPEC/receptors HQ_{NOAEL}<1. **Small Ranging Receptors:** Negligible risk; < NOAEL for all locations for meadow vole and short-tailed shrew, except $TEC_{2,3,7,8\text{-TCDD}}$ for short-tailed shrew (HQ_{NOAEL}=1.1; HQ_{LOAEL} <1)	**Negligible**	No further evaluation on the basis of terrestrial exposure.

Table 8-1
Summary of BERA Findings - Terrestrial Exposure Areas
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Exposure Area	Direct Contact Exposure Summary			Wildlife Exposure Summary			Preliminary Conclusions and Recommendations
	Soil Invertebrates	Terrestrial Plant Community	Overall Direct Contact Risk	Birds	Mammals	Overall Wildlife Risk	
Flathead River Riparian Area	Negligible risk; maximum exposure < LOEC.	Negligible risk; maximum exposure < LOEC.	**Negligible**	**Maximum scenario:** Negligible risk to birds foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1; maximum cyanide HQ_{NOAEL}=1.5. **Refined scenario:** Negligible risk to birds foraging exclusively within the exposure area; Refined HQ_{NOAEL}<1.	**Maximum scenario:** Negligible risk to mammals foraging exclusively within the exposure area; maximum HQ_{NOAEL}<1 for modeled COPEC/receptors **Refined scenario:** Negligible risk to mammals foraging exclusively within the exposure area; Refined HQ_{NOAEL}<1. **Small Ranging Receptors:** Negligible risk; < NOAEL for all locations for meadow vole and short-tailed shrew.	**Negligible**	No further evaluation on the basis of terrestrial exposure.
Incremental Soil Sampling (ISS) Area	Moderate risk. Limited risk to soil invertebrates. Maximum EPCs > LOEC for copper (HQ_{LOEC}=1.7) and zinc HQ_{LOEC}=1.8). Maximum EPCs > NOECs for LMW PAHs (HQ_{NOEC}=74.6) and HMW PAHs (HQ_{NOEC}=68.3); LOECs not identified for LMW and HMW PAHs. Refined EPC > LOEC for copper (HQ_{LOEC}=1.4); refined EPCs > NOECs for LMW PAHs (HQ_{NOEC}=3.0) and HMW PAHs (HQ_{NOEC}=4.3); LOECs not identified for LMW and HMW PAHs.	Negligible risk; Maximum EPC slightly exceeds LOEC for barium (HQ_{LOEC}=1.2), copper (HQ_{LOEC}=1.8), selenium (HQ_{LOEC}=4.4), and zinc (HQ_{LOEC}=2.1). Refined EPCs < LOEC, except slight exceedance of copper (HQ_{LOEC}=1.5).	**Moderate**	Exposure evaluated as part of Central Landfills Area and Main Plant Area evaluations.	**Small Ranging Receptors:** Potential for adverse effects greatest for small mammals in northern portion of Main Plant within the Operational Area footprint; short-tailed shrew exposure > LOAEL at 10 of 43 grids and meadow vole exposure > LOAEL at 1 of 43 grids.	**Moderate**	Impacts from PAHs and metals to local terrestrial plant and invertebrate communities via direct contact and small-ranging mammalian populations via direct and indirect ingestion possible. Ecological exposure pathways limited under current, disturbed conditions; however, further evaluation of exposure may be warranted if future site conditions return these areas to a more naturalized habitat condition that supports ecological receptor populations.

Notes:
COPEC, Constituent of potential ecological concern.
EPC, Exposure point concentrations
HMW PAHs, High molecular weight polycyclic aromatic hydrocarbons
HQ, Hazard quotient; ratio of direct contact EPC to NOEC/LOEC or estimated daily dose to NOAEL/LOAEL.
LMW PAHs, Low molecular weight polycyclic aromatic hydrocarbons
LOAEL, Lowest observed adverse effect level dose.
LOEC, Lowest observed effect concentration.
NOAEL, No observed adverse effect level dose.
NOEC, No observed effect concentration.
Maximum scenario, Represents worst case exposure scenario by assuming maximum concentrations as EPCs in direct contact evaluation or inputs to EDD doses for wildlife ingestion pathways.
Refined scenario, Represents conservative estimate of average exposure scenario by assuming upper confidence limit of the mean (UCL_{mean}) concentrations as EPCs in direct contact evaluation or inputs to EDD doses for ingestion pathways.

Table 8-2
Summary of BERA Findings - Transitional Exposure Areas - Terrestrial Scenario
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Exposure Area	Direct Contact Exposure Summary		Overall Direct Contact Risk	Wildlife Exposure Summary		Overall Wildlife Risk	Preliminary Conclusions and Recommendations
	Soil Invertebrates	Terrestrial Plant Community		Birds	Mammals		
North Percolation Ponds	High Risk. Maximum EPCs > NOEC for LMW PAHs (HQ_{NOEC}=307 to 311) and HMW PAHs (HQ_{NOEC}=763); maximum EPCs for cyanide, fluoride, and metals < LOEC. Refined EPCs result in HQ_{NOEC} > 100 for LMW and HMW PAHs.	High Risk. HQ_{LOEC} > 1 based on maximum exposure to 7 metals, with HQ_{LOEC} values from 1.1 (zinc and selenium) to 9.2 (thallium). Refined EPCs > LOEC for nickel (HQ_{LOEC}=1.3), thallium (HQ_{LOEC}=3.8), and vanadium (HQ_{LOEC}=1.4). Exposure to LMW and HMW PAHs is uncertain due to lack of NOEC/LOEC benchmarks.	**High**	**Maximum scenario:** High Risk**.** Potential for adverse effects to birds exposed to cyanide, barium, nickel, selenium, vanadium, LMW PAHs, HMW PAHs, (HQ_{LOAEL}=1.1 to 704) if foraging at maximum exposure exclusively within the North Percolation Pond **Refined scenario:** High Risk. Potential for adverse effects to all avian receptors exposed to nickel, selenium, vanadium, LMW PAHs, and HMW PAHs based on exclusive foraging at refined EPCs (HQ_{LOAEL}=1.8 to 146.5).	**Maximum scenario:** High Risk. Potential for adverse effects to mammals exposed to nickel, LMW PAHs, HMW PAHs, (HQ_{LOAEL}=2.3 to 65) if foraging at maximum exposure exclusively within the North Percolation Pond **Refined scenario:** High Risk. Potential for adverse effects to the Canada lynx, grizzly bear, meadow vole, and short-tailed shrew exposed to nickel and HMW PAHs based on exclusive foraging at refined EPCs (HQ_{LOAEL}=2.3 to 23). HQ_{LOAEL} values below 1 for all receptors except the meadow vole (HMW PAHs) and short-tailed shrew (nickel and HMW PAHs) when area use factor included.	**High**	Greatest potential for adverse effects is associated with exposure to PAHs and metals, particularly in the North-East Pond. Risk due to direct contact and direct and indirect ingestion pathways is high. Further risk assessment may not be beneficial, particularly in the North-East Pond; evaluate future use of North Percolation Pond prior to developing ERA recommendations.
South Percolation Ponds	Negligible risk; Maximum EPCs < LOEC, except for copper (HQ_{LOEC}=1.3) and mercury (HQ_{LOEC}=2.8). Refined EPCs < LOEC.	Negligible risk; Maximum EPCs < LOEC, except for barium (HQ_{LOEC}=3.7) and copper (HQ_{LOEC}=1.4). Refined EPCs < LOEC, except for barium (HQ_{LOEC}=2.5).	**Negligible**	**Maximum scenario:** Minimal Risk**.** Low potential for adverse effects to birds exposed to copper and BEHP (HQ_{LOAEL}=1.6 to 1.7) if foraging at maximum exposure exclusively within the South Percolation Pond; all other COPEC/receptors HQ_{LOAEL}<1 **Refined scenario:** Minimal Risk. Low potential for adverse effects to American woodcock (HQ_{LOAEL}=1.2) and yellow-billed cuckoo (HQ_{NOAEL}=1.7) foraging at refined EPCs; all other COPEC HQ_{LOAEL}<1.	**Maximum scenario:** Negligible risk to mammals foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1 **Refined scenario:** Negligible risk to mammals foraging exclusively within the exposure area; short-tailed shrew had HQNOAEL > 1 for cadmium, copper, and nickel, but all HQ_{LOAEL}<1 based on refined EPCs.	**Minimal**	No further evaluation on the basis of terrestrial exposure.
Cedar Creek Reservoir Overflow Ditch	Negligible risk; maximum exposure < LOEC.	Negligible risk; maximum exposure < LOEC, except for slight exceedances of barium (HQ_{LOEC}=1.1) and manganese (HQ_{LOEC}=1.5).	**Negligible**	**Maximum scenario:** Negligible risk to birds foraging exclusively within the exposure area; maximum HQ_{NOAEL}=1 (zinc for yellow-billed cuckoo). **Refined scenario:** Negligible risk; < LOAEL for all receptors/COPECs based on refined EPCs.	**Maximum scenario:** Negligible risk. Mammals foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1. **Refined scenario:** Negligible risk; HQ_{LOAEL}<1 for all receptor/COPECs.	**Negligible**	No further evaluation on the basis of terrestrial exposure.
Northern Surface Water Feature	Negligible risk; maximum exposure < LOEC.	Negligible risk; maximum exposure < LOEC, except for slight exceedances of barium (HQ_{LOEC}=2.3).	**Negligible**	**Maximum scenario:** Negligible potential for adverse effects to terrestrial birds. All HQ_{LOAEL}<1 based on maximum EPCs. **Refined scenario:** Negligible risk; < LOAEL for all receptors/COPECs based on refined EPCs..	**Maximum scenario:** Negligible risk. Mammals foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1. **Refined scenario:** Negligible risk; HQ_{LOAEL}<1 for all receptor/COPECs.	**Negligible**	No further evaluation on the basis of terrestrial exposure.

Table 8-3
Summary of BERA Findings - Transitional Exposure Areas - Aquatic Scenario
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Exposure Area	Direct Contact Exposure Summary			Overall Direct Contact Risk	Wildlife Exposure Summary		Overall Wildlife Risk	Preliminary Conclusions and Recommendations
	Benthic/Pelagic Invertebrate Communities	Aquatic Plant Community	Fish/Herptiles		Birds	Mammals		
North Percolation Ponds	**Surface Water:** High Risk. Maximum fluoride exceed LOEC for invertebrates (HQ_{LOEC}=5.2 to 5.5) and fish/amphibian communities (HQ_{LOEC}=3.6 to 3.7); maximum metals concentrations exceed LOEC for aluminum, barium, cadmium, copper, zinc [HQ_{LOEC}=2.3 to 785 (unfiltered Al)]; maximum concentrations of 7 PAH compounds exceed NOEC (FCV) with HQ_{NOEC}=1.3-14.8. **Sediment:** High Risk. PAH $ESBTU_{34}$>1 at 24 of 30 stations; PAH $ESBTU_{34}$>10 at 13 of 30; Maximum EPCs exceed LOECs for cyanide (HQ_{LOEC}=137) and several metals, with HQ_{LOEC} values ranging from 1.2 (selenium) to 26.0 (nickel). Refined EPCs > LOEC for cyanide (HQ_{LOEC}=41.2) and lead (HQ_{LOEC}=7.5).			**High**	**Maximum scenario:** High Risk. Potential for adverse effects to birds exposed to cyanide, barium, nickel, selenium, vanadium, LMW PAHs, HMW PAHs, (HQ_{LOAEL}=1.1 to 704) if foraging at maximum exposure exclusively within the North Percolation Pond **Refined scenario:** High Risk. Potential for adverse effects to American dipper exposed to selenium, vanadium, LMW PAHs, and HMW PAHs and belted kingfisher exposed to HMW PAHs based on exclusive foraging at refined EPCs (HQ_{LOAEL}=1.4 to 284).	**Maximum scenario:** Negligible risk to mink foraging exclusively within the exposure area at maximum EPCs (HQ_{NOAEL}<1) **Refined scenario:** Negligible risk to mink foraging exclusively within the exposure area at refined EPCs (HQ_{NOAEL}<1)	**High**	Greatest potential for adverse effects via direct contact exposure to fluoride, metals, and PAHs in surface water and sediment, particularly in the North-East Pond. High risk associated with birds foraging in exposure area. Further risk assessment may not be beneficial, particularly in the North-East Pond; evaluate future use of North Percolation Pond prior to developing ERA recommendations.
South Percolation Ponds	**Surface Water:** Moderate Risk. Maximum EPCs > LOEC for total cyanide (HQ_{LOEC}=3.1 to 6.3), aluminum, barium (HQ_{LOEC}=8.0 to 20.2), copper, and iron (HQ_{LOEC}=2.3); sample-specific LOEC exceeded in for aluminum in 2/17 filtered samples (HQ_{LOEC}=1.0-3.1), aluminum in 2/26 unfiltered samples (HQ_{LOEC}=1.2 to 11.7), filtered copper in 1/17 samples (HQ_{LOEC}=1.1-1.2), unfiltered copper in 1/26 samples (HQ_{LOEC}=1.1). Refined EPCs > LOEC for cyanide (HQ_{LOEC}=2.4) and barium (HQ_{LOEC}=8.0 to 20.2). **Sediment:** Moderate Risk. Maximum EPCs > LOEC for cyanide (HQ_{LOEC}=16.4) and several metals (HQ_{LOEC}=1.1 to 5.0); Refined EPCs > LOEC for cyanide (HQ_{LOEC}=4.4), barium (HQ_{LOEC}=2.1), and copper (HQ_{LOEC}=1.4). AVS-SEM/f_{oc} not indicative of adverse effects to metals; **Pore water:** Moderate Risk. Aluminum and copper < LOEC in pore water samples; maximum EPC for barium exceeds LOEC (HQ_{LOEC}=10.8).			**Moderate**	**Maximum scenario:** Minimal Risk. Low potential for adverse effects to birds exposed to barium and copper (HQ_{LOAEL}=2.3 to 3.5) if foraging at maximum exposure exclusively within the South Percolation Pond; all other COPEC/receptors HQ_{LOAEL}<1 **Refined scenario:** Minimal Risk. Low potential for adverse effects to American dipper exposed to barium (HQ_{LOAEL}=2.3) foraging at refined EPCs; all other COPEC HQ_{LOAEL}<1 for American dipper and belted kingfisher.	**Maximum scenario:** Negligible risk to mammals foraging exclusively within the exposure area; maximum HQ_{NOAEL}<1 **Refined scenario:** Negligible risk to mammals foraging exclusively within the exposure area; H_{QNOAEL}<1 based on refined EPCs.	**Minimal**	Greatest potential for adverse effects via direct contact exposure to cyanide, metals, and PAHs in surface water. Evaluate potential for minimizing stormwater discharge with elevated concentrations of cyanide, aluminum, and other COPECs to the South Percolation Ponds.
Cedar Creek Reservoir Overflow Ditch	**Surface Water:** Negligible risk. Maximum EPCs > LOEC for aluminum, barium (HQ_{LOEC}= 5.4 to 5.6), and manganese (HQ_{LOEC}= 1.6). Aluminum LOEC (NRWQC CMC) exceeded in 1 of 27 samples (HQ_{LOEC}=6.5); filtered aluminum < NOEC. Refined exposure to barium results in HQ_{LOEC}= 2.6 to 2.7. Barium concentrations consistent upstream to downstream across site, with the exception of Oct 2018 result at CFSWP-039, indicating potential upgradient conditions. **Sediment:** Minimal Risk. Limited potential for adverse effects to benthic invertebrates associated with exposure to cyanide, manganese, and PAHs. Maximum EPCs > LOEC for cyanide (HQ_{LOEC} = 1.5), manganese (HQ_{LOEC} = 1.5), and PAHs (ESBTU = 7.7 to 21.2) . PAH $ESBTU_{34}$ < 1 for all stations except CFSB-284 (tPAHs=7.4; low TOC=0.006%). Refined EPCs < 1 for all COPECs, except manganese (HQ_{LOEC} = 1.2).			**Minimal**	**Maximum scenario:** Negligible risk to birds foraging exclusively within the exposure area; maximum HQ_{LOAEL}=1.1 (barium for American dipper). **Refined scenario:** Negligible risk; < LOAEL for all receptors/COPECs based on refined EPCs.	**Maximum scenario:** Negligible risk. Mammals foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1. **Refined scenario:** Negligible risk; HQ_{LOAEL}<1 for all receptor/COPECs.	**Negligible**	No further evaluation on the basis of aquatic exposure.

Table 8-3
Summary of BERA Findings - Transitional Exposure Areas - Aquatic Scenario
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Exposure Area	Direct Contact Exposure Summary			Overall Direct Contact Risk	Wildlife Exposure Summary		Overall Wildlife Risk	Preliminary Conclusions and Recommendations
	Benthic/Pelagic Invertebrate Communities	Aquatic Plant Community	Fish/Herptiles		Birds	Mammals		
Northern Surface Water Feature	**Surface Water:** Minimal Risk. Maximum EPCs > LOEC for aluminum and barium (HQ_{LOEC}=5.9 to 6.3); Aluminum LOEC (NRWQC CMC) exceeded in 2 of 16 samples (HQ_{LOEC}=1.2 to 1.9); filtered aluminum < NOEC. Refined EPC > LOEC for barium (HQ_{LOEC} = 3.8). **Sediment:** Minimal Risk. Maximum EPCsv > LOEC for barium (HQ_{LOEC} = 3.0) and manganese (HQ_{LOEC} = 1.5); maximum EPCs < LOEC for other COPECs. Refined EPC for barium > LOEC (HQ_{LOEC} = 2.0). PAH $ESBTU_{34}$ < 1 for all stations. **Pore water:** Minimal Risk. Maximum barium EPC > LOEC (HQ_{LOEC}=8.0); maximum EPCs > LOEC for other COPECs.			**Minimal**	**Maximum scenario:** Limited potential for adverse effects to American dipper foraging exclusively at maximum EPCs for barium (HQ_{LOAEL}=3.3) and selenium (HQ_{LOAEL}=3.4). HQ_{LOAEL}<1 for other receptors/COPECs based on maximum EPCs. **Refined scenario:** Limited potential for adverse effects to American dipper foraging exclusively at refined EPCs for barium (HQ_{LOAEL}=2.1)and selenium (HQ_{LOAEL}=1.2); HQ_{LOAEL}<1 for other receptors/COPECs based on refined EPCs.	**Maximum scenario:** Negligible risk. Mammals foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1. **Refined scenario:** Negligible risk; HQ_{LOAEL}<1 for all receptor/COPECs.	**Minimal**	No further evaluation on the basis of aquatic exposure.

Notes:
COPEC, Constituent of potential ecological concern.
EPC, Exposure point concentrations
HMW PAHs, High molecular weight polycyclic aromatic hydrocarbons
HQ, Hazard quotient; ratio of direct contact EPC to NOEC/LOEC or estimated daily dose to NOAEL/LOAEL.
LMW PAHs, Low molecular weight polycyclic aromatic hydrocarbons
LOAEL, Lowest observed adverse effect level dose.
LOEC, Lowest observed effect concentration.
NOAEL, No observed adverse effect level dose.
NOEC, No observed effect concentration.
Maximum scenario, Represents worst case exposure scenario by assuming maximum concentrations as EPCs in direct contact evaluation or inputs to EDD doses for wildlife ingestion pathways.
Refined scenario, Represents conservative estimate of average exposure scenario by assuming upper confidence limit of the mean (UCL_{mean}) concentrations as EPCs in direct contact evaluation or inputs to EDD doses for ingestion pathways.

Table 8-4
Summary of BERA Findings - Aquatic Exposure Areas
Baseline Ecological Risk Assessment
Columbia Falls Aluminum Company
Columbia Falls, Montana

Exposure Area	Direct Contact Exposure Summary			Overall Direct Contact Risk	Wildlife Exposure Summary		Overall Wildlife Risk	Preliminary Conclusions and Recommendations
	Benthic/Pelagic Invertebrate Communities	Aquatic Plant Community	Fish/Herptiles		Birds	Mammals		
Flathead River	**Surface Water:** Moderate risk. Total cyanide exceeds LOEC (acute) in maximum and refined exposure scenarios; free cyanide concentrations result in HQ_{LOEC} 1.1 to 1.2 based on refined exposure scenario. Refined exposure estimate for barium results in HQ_{LOEC}=2.7-3.0. Aluminum LOEC (NRWQC CMC) exceeded in 8 of 76 samples (HQ_{LOEC}=1.6 to 17.7); filtered aluminum < NOEC. **Sediment:** Minimal Risk. Potential exposure to cyanide associated with aqueous exposure to pore water; potential exposure to tPAHs primarily associated with sampling stations in the Backwater Seep Sampling Area with $ESBTU_{34}$ values < 1, except for CFSDP-036 on the Flathead River that had tPAH = 1.35 mg/kg with low TOC (0.01 %) **Pore water:** Moderate Risk. Maximum cyanide (free) exposure in Backwater Seep Sampling Area sampling stations exceed NOEC and LOEC (acute), with HQ_{NOEC} and HQ_{LOEC} of 12.0 and 2.8, respectively. Maximum exposure to barium results in HQLOEC=6.7. Negligible exposure to fluoride (maximum HQ_{NOEC}=1.7; HQ_{LOEC}<1).			**Moderate**	**Maximum scenario:** Negligible risk to birds foraging exclusively within the exposure area at maximum EPCs; maximum HQ_{LOAEL}<1. **Refined scenario:** Negligible risk to birds foraging exclusively within the exposure area; HQ_{LOAEL}<1 based on refined EPCs.	**Maximum scenario:** Negligible risk to mammals foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1 for all receptors/COPECs. Maximum EPC for HMW PAHs > NOAEL (HQ_{NOAEL}= 6.7). **Refined scenario:** Negligible risk based on refined EPCs; HQ_{NOAEL} for HMW PAHs = 1.5 for mink, but HQ_{LOAEL}<1.	**Negligible**	Greatest potential for adverse effects via direct contact exposure is associated with exposure to cyanide, aluminum, and barium in surface water and pore water at stations in the Backwater Seep Sampling Area. Further evaluation of chronic, direct contact exposure to cyanide in surface water and pore water may be warranted.
Flathead River Excluding Backwater Seep Area	**Surface Water:** Minimal Risk. No exceedances of NOEC for total cyanide or free cyanide. Unfiltered aluminum exceeds LOEC (NRWQC CMC) in 3 of 40 samples (HQ_{LOEC}=3.5 to 17.7); filtered aluminum < NOEC. Refined exposure estimate for barium results in HQ_{LOEC}=2.1-2.4. **Sediment:** Minimal Risk. Potential exposure to tPAHs with $ESBTU_{34}$ values > 1 limited to CFSDP-036 (tPAH = 1.35 mg/kg; TOC 0.01 %); AVS-SEM/f_{oc} not indicative of adverse effects to metals; cyanide (free and total) < NOEC. **Pore water:** Minimal Risk. Maximum exposure to barium results in HQ_{LOEC}=6.7; barium concentrations consistent upgradient to downgradient, indicating concentrations are representative of upgradient/background conditions. Cyanide (free and total) < NOEC.			**Minimal**	**Maximum scenario:** Negligible risk to birds foraging exclusively within the exposure area at maximum EPCs; maximum HQ_{LOAEL}<1. **Refined scenario:** Negligible risk to birds foraging exclusively within the exposure area; HQ_{LOAEL}<1 based on refined EPCs.	**Maximum scenario:** Negligible risk to mammals foraging exclusively within the exposure area; maximum HQ_{LOAEL}<1 for all receptors/COPECs. Maximum EPC for HMW PAHs > NOAEL (HQ_{NOAEL}= 6.7). **Refined scenario:** Negligible risk based on refined EPCs (HQ_{NOAEL}<1).	**Negligible**	Potential for adverse effects is substantially lower in Flathead River sampling stations outside of the Backwater Seep Sampling Area. No further evaluation on the basis of ecological risk for the Flathead River outside of the Backwater Seep Sampling Area.
Flathead River Riparian Channel	**Surface Water:** Moderate Risk. Total cyanide exceeds LOEC (NRWQC CMC) in maximum and refined exposure scenarios; free cyanide concentrations result in HQ_{LOEC} 2.0 to 2.8 based on refined exposure scenario. Refined exposure estimate for barium results in HQ_{LOEC}=6.9-16.1. Aluminum NOEC (NRWQC CCC) exceeded in 6 of 15 samples (HQ_{NOEC}=1.2-41.6); Aluminum LOEC (NRWQC CMC) exceeded in 3 of 15 samples (HQ_{LOEC}=1.8-10.7); filtered aluminum < LOEC. Unfiltered copper > NOEC and LOEC in 2 of 15 samples (HQ_{LOEC}=1.0-2.0); filtered copper < NOEC. **Sediment:** Minimal Risk. Potential exposure to cyanide associated with aqueous exposure to pore water; potential exposure to tPAHs primarily associated with CFSDP-029 nearest the Backwater Seep Sampling Area ($ESBTU_{34}$ = 4.0); $ESBTU_{34}$ values < 1 at other stations. **Pore water:** Moderate Risk.Cyanide (free) exceed LOEC (NRWQC CMC) in 3 of 6 samples (max HQ_{LOEC}=7.4 at CFSDP-029); Free cyanide exceeds NOEC in 4 of 6; Maximum barium EPC results in HQ_{LOEC}=10.1. Other COPECs < LOEC; PAHs < NOEC. Aluminum not identified as as refined COPEC.			**Moderate**	Not evaluated as a separate wildlife exposure area.	Not evaluated as a separate wildlife exposure area.	**Not Applicable**	Greatest potential for adverse effects via direct contact exposure is associated with exposure to cyanide, aluminum, and barium in surface water and pore water. Further evaluation of chronic, direct contact exposure to cyanide in surface water and pore water may be warranted.

Table 8-4

Subject: **Technical Memorandum: Proposed Refined Ecological Screening Values to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site**
Former Columbia Falls Aluminum Company Aluminum Reduction Facility
Columbia Falls, Montana

On behalf of Columbia Falls Aluminum Company, LLC (CFAC), Roux Environmental Engineering and Geology, D.P.C. (Roux) and EHS Support, LLC prepared the attached Technical Memorandum for Proposed Refined Ecological Screening Values (ESVs) to Support the Baseline Ecological Risk Assessment (BERA) for the CFAC Superfund Site in Columbia Falls, Montana. This memorandum has been prepared as part of the ongoing Remedial Investigation/Feasibility Study (RI/FS) being conducted pursuant to the Administrative Settlement Agreement and Order on Consent (AOC) dated November 30, 2015 between CFAC and the United States Environmental Protection Agency (USEPA) (CERCLA Docket No. 08-2016-0002).

Should there be any questions or comments on this submission, please do not hesitate to contact me at (631) 230-2300.

Sincerely,

Laura Jensen

Re: *Technical Memorandum: Proposed Refined Ecological Screening Values (ESVs) to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site*
Former Columbia Falls Aluminum Company Aluminum Reduction Facility
Columbia Falls, Montana

Introduction

This technical memorandum describes the approach for developing refined ecological screening values (ESVs) to support the selection of constituents of potential ecological concern (COPECs) in the Baseline Ecological Risk Assessment (BERA) for the Columbia Falls Aluminum Company (CFAC) Superfund Site in Columbia Falls, Montana. This technical memorandum was prepared as an interim deliverable to supplement the general risk assessment framework provided in the *Baseline Ecological Risk Assessment Work Plan* (BERA WP) submitted to the United States Environmental Protection Agency (USEPA) and Montana Department of Environmental Quality (MDEQ) in November 2017 and revised in May 2018 (EHS Support, 2018a).

As stated in the BERA WP, refinement of COPECs identified in the Screening-Level Ecological Risk Assessment (SLERA) will be performed as part of the BERA Problem Formulation (EHS Support, 2018a). COPEC refinement in the BERA Problem Formulation is consistent with USEPA *The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessment* (USEPA, 2001). The refinement of COPECs identified in the SLERA is a fundamental step in the BERA Problem Formulation to focus BERA analyses on COPECs that are most likely to drive risk management decision-making for the Site. The intent of the refinement is to focus and streamline the overall Ecological Risk Assessment Guidance for Superfund (ERAGS) process by considering additional components early in the BERA process.

COPEC refinement will be performed on the combined datasets from the Phase I and Phase II Site Characterization sampling for ecological exposure media (EHS Support, 2018a). Screening of constituents using the combined Phase I and Phase II datasets for each exposure area and exposure medium will be based on a tiered approach:

1) Maximum exposure point concentrations (EPCs) of constituents in Phase I and Phase II Site Characterization datasets for each ecological exposure area will be initially compared to minimum ESVs presented in the SLERA.
2) Constituents identified as COPECs in the initial screening will be refined based on the re-screening of COPECs using comparisons of maximum EPCs to refined ESVs.

The technical memorandum presents the rationale for selecting refined ESVs to support the COPEC refinement process in the BERA. The comparisons of maximum exposure concentrations to minimum ESVs, consistent with Step 1 of the COPEC refinement process, have a low probability of resulting in false negatives in the screening process (i.e., eliminating COPECs that may cause adverse effects due to exposure). However, the minimum ESVs applied in Step 1 of the screening do not represent the range of no observed effect concentration (NOEC) endpoints that are protective of chronic exposure. Therefore, these comparisons cannot be used to conclude that exposure to a COPEC is likely to result in adverse effects. The findings of Step 1 of the screening process only indicate that certain COPECs and associated exposure pathways require further evaluation. Refined ESVs were identified to represent values that are protective of chronic exposure but represent a broader range of NOEC endpoints that will be used to focus the list of COPECs requiring further evaluation in the BERA.

Refined ESVs are identified in this technical memorandum for the list of COPECs identified for soil, sediment, and surface water in the SLERA based on the screening of Phase I Site Characterization data and additional COPECs identified in the BERA WP based on detected constituents lacking ESVs. If additional COPECs are identified during Tier 1 screening once the Phase I and Phase II Site Characterization datasets are combined, the selection of refined ESVs for the Tier 2 screening will follow the approach outlined in this technical memorandum for additional COPECs. The following sections describe the technical rationale for the selection of refined soil, sediment, and surface water ESVs in the COPEC refinement process in the BERA Problem Formulation.

Refined Soil ESVs

Refined soil ESVs will be based on peer-reviewed, multi-trophic level soil screening criteria, consistent with the USEPA approach for deriving Ecological Soil Screening Levels (Eco-SSLs). Eco-SSLs were derived as risk-based soil screening levels through a peer review process for the protection of multiple terrestrial receptor categories (USEPA, 2005):

- Terrestrial plants
- Soil invertebrates
- Birds
- Mammals

Like Eco-SSLs, the Los Alamos National Laboratory (LANL) ECORISK Database (Release 4.1) presents conservative screening values based on modeled exposure for receptors in various trophic levels (LANL, 2017). Consistent with the Eco-SSL approach, the ECORISK Database used geometric mean concentrations of NOEC endpoints as screening criteria for each terrestrial receptor category. These LANL screening values were used to supplement the Eco-SSL values to develop refined ESVs. Screening values for the various terrestrial trophic level receptors evaluated in both the ECORISK Database and the Eco-SSL guidance were pooled, and the minimum screening criterion for each COPEC was identified as the refined soil ESV (**Table 1**).

Refined ESVs for chemicals lacking screening values in the LANL and/or Eco-SSL datasets were identified from other available sources in the literature. USEPA Region 5 ecological screening levels (ESLs) (USEPA, 2003a) were preferentially used for this purpose. ESLs provide protective benchmarks for contaminants in soil, and consider direct, as well as indirect (i.e., food-chain) exposure pathways. If ESLs were not available, other accepted sources for soil benchmarks were also considered (e.g., Efroymson et al., 1997a; Efroymson et al., 1997b).

Given that refined ESVs are protective of direct contact and indirect ingestion exposure pathways, constituents with maximum EPCs lower than the refined ESVs will not be evaluated further in the BERA. In the absence of sufficient data to refine soil ESVs, the conservative minimum ESV used in the SLERA will be retained. However, further literature review may be conducted to refine ESVs for these COPECs in the BERA Problem Formulation. Refined soil ESVs for the initial COPECs identified in the SLERA and BERA Work Plan are presented in **Table 1**; the rationale for the selection of refined ESVs is presented in the following sections.

Inorganic COPECs

With one exception, the lowest screening value from the LANL ECORISK Database or the USEPA Eco-SSLs will be used as refined ESVs for metal and other inorganic COPECs (**Table 1**). The refined ESV for chromium was the only metal for which the lowest screening value from the two primary sources was not selected.

Refined ESVs for chromium will be identified from toxicity studies conducted based on exposure to the corresponding form of chromium measured in soils at the Site. Chromium is present primarily in the trivalent [Cr(III)] oxidation state under typical soil conditions (USEPA, 2008a). Hexavalent chromium [Cr(VI)] is only stable in oxidizing soils at moderate pH levels, whereas the Cr(III) is the dominant species under moderately oxidizing to reducing conditions. Additionally, the reduction-oxidation transformations between the two valence states are not fully reversible. Cr(VI) will reduce to Cr(III) in a reducing environment, but once reduced, Cr(III) will not readily re-oxidize to Cr(VI) under oxidizing conditions.

A select number of soil borings will be analyzed for Cr(VI) and total chromium in the Phase II Site Characterization to reduce uncertainty in the risk assessment of chromium in site soils (Roux Associates, 2018a). Cr(III) concentrations will be estimated as the difference in concentrations between total chromium and Cr(VI) results. Estimated concentrations of Cr(III) and measured concentrations of Cr(VI) will be used to develop a site-specific ratio of Cr(III):Cr(VI). The site-specific Cr(III):Cr(VI) ratio will be applied to Phase I and Phase II samples analyzed only for total chromium to estimate the relative concentration of Cr(III) and Cr(VI) in the sample. Refined ESVs derived based on Cr(VI) toxicity studies will be applied to the measured or estimated Cr(VI) concentrations in soil; refined ESVs for Cr(III) or total chromium will be applied to estimated concentrations of Cr(III) in soil (**Table 1**).

Numeric ESVs were not identified for aluminum and iron in soil in the Eco-SSL or LANL ECORISK database. USEPA Eco-SSL guidance indicates that total aluminum measurements are not considered suitable or reliable for the prediction of potential toxicity and bioaccumulation of aluminum in soils (USEPA, 2003b). The Eco-SSL guidance indicates that potential ecological risks associated with aluminum are based on soil pH, with aluminum being identified as a COPEC only at sites where soil pH is less than

5.5 (USEPA, 2003b). Therefore, the screening of aluminum as a COPEC in site soils will be based on measured soil pH values as an indication of the potential bioavailability and toxicity of aluminum concentrations. Like aluminum, numeric Eco-SSLs were not derived for iron because its bioavailability and toxicity are dependent upon site-specific conditions, including soil pH. In well-aerated soils with pH values between 5 and 8, iron is not expected to be toxic to plants (USEPA, 2003c). Consistent with Eco-SSL guidance, the potential bioavailability and toxicity of iron will be based on site-specific measurements of soil pH.

For metal COPECs, mean concentrations representative of unimpacted soils analyzed as part of the Montana State Background Investigation (MSBI; Hydrometrics, 2013) were presented in the BERA Work Plan to provide regional context to concentrations of inorganic chemicals detected in soil. Further characterization of background conditions is proposed as part of the Phase II Site Characterization (Roux Associates, 2018b; Roux Associates, 2018c). Site-specific background data collected as part of the Phase II Site Characterization will supplant MSBI regional soil data in the COPEC refinement process conducted as part of the BERA Problem Formulation. In addition to comparisons to refined ESVs, concentrations of metals in soil will also be compared to representative, site-specific background concentrations to evaluate whether detected concentrations are consistent with naturally occurring concentrations.

As stated in the BERA Work Plan and consistent with *The Role of Screening-Level Risk Assessments and Refining Contaminants of Concern in Baseline Ecological Risk Assessments* (USEPA, 2001), representative background concentrations calculated from Phase II Site Characterization background data will be used as the refined ESV to evaluate the need for further consideration of essential nutrients in the BERA. Because the soil background data from the Phase II Site Characterization sampling have not been compiled and representative background concentrations for each metal have not yet been calculated or approved, only the refined ESVs based on toxicological effects are presented in this interim deliverable.

Organic COPECs

LANL and/or USEPA Eco-SSLs values were available for many organic COPECs (**Table 1**). For the organic COPECs lacking LANL or Eco-SSL values, refined ESVs will be based on USEPA Region 5 ESLs (USEPA, 2003a) for 16 non-polycyclic aromatic hydrocarbons (PAH) organic compounds and based on an Oak Ridge National Laboratory (ORNL) benchmark for 4-nitrophenol in soil (Efroymson et al., 1997a). As shown in **Table 1**, the minimum ESV used in the SLERA was retained for organic COPECs lacking refined ESVs from these sources.

Exposure to the mixture of 17 dioxin/furan compounds analyzed in surficial (0-0.5 ft) and shallow (0.5-2 ft) soil samples will be evaluated relative to the toxicity of 2,3,7,8-tetrachlorinated dibenzo-p-dioxin (2,3,7,8-TCDD) using toxicity equivalency factors (TEFs) developed for birds and mammals by the World Health Organization (Van den Berg et al., 2006; Van den Berg et al., 1998; USEPA, 2008b). For dioxin/furan screening, measured concentrations of the 17 dioxin/furan compounds in surface and shallow soil samples will be multiplied by compound-specific TEFs to calculate toxicity equivalence concentrations to 2,3,7,8-TCDD ($TEC_{2,3,7,8\text{-}TCDD}$) for each compound, assuming consistent bioaccumulation for the 17 dioxin/furan compounds. The summed $TEC_{2,3,7,8\text{-}TCDD}$ values for each sample will be compared to the refined ESV for 2,3,7,8-TCDD, which is identified in **Table 1** as 0.00000029 mg/kg based on the protection of mammalian wildlife in the LANL ECORISK database. Multiple options are available for addressing surrogate values for nondetect congener results (USEPA, 2008b). The CFAC BERA will use 0,

0.5 x the method detection limit (MDL) and the MDL as three scenarios to bracket the range of possible concentrations owing to contributions of results that are nondetect. The MDL represents the lower limit of concentrations detectable by the analytical method. Therefore, any concentrations above the MDL are typically detectable values, and are recorded at the concentration reported by the laboratory. Thus, the MDL represents a conservative upper limit for the potential concentration of dioxin in a sample producing a nondetect result. In some cases, dioxin congener results that had a reported laboratory value were flagged with a laboratory qualifier "B" (indicating blank contamination) and a validation qualifier of "U" (indicating that the influence of the blank contamination compromised the confidence of determining if the constituent was present in the sample at all). In such cases, the reported laboratory value will conservatively be used as the surrogate value for the nondetect rather than the MDL. All reported and surrogate values will then be multiplied by the appropriate bird or mammal TEF, and the TEF-adjusted concentrations will then be summed to develop the $TEC_{2,3,7,8\text{-}TCDD}$.

Given that some organic COPECs in soils may be derived from regional sources unrelated to site activities (e.g., PAHs), representative background concentrations derived from the background investigation that will be conducted as part of the Phase II Site Characterization sampling will be compared to measured concentrations in site datasets to further refine the list of organic COPECs for evaluation in the BERA (Roux Associates, 2018c).

Refined Sediment ESVs

Refined ESVs for sediment will be based primarily on consensus-based criteria and equilibrium partitioning (EqP)-based criteria protective of direct contact toxicity pathways to benthic organisms. Given that sediment ESVs are not derived for the protection of indirect exposure through ingestion (e.g., bioaccumulation/biomagnification pathways), potential ingestion exposure pathways for detected bioaccumulative COPECs will be evaluated consistent with the approach outlined in the *Technical Memorandum: Proposed Wildlife Exposure Modeling Approach to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site* (EHS Support, 2018b).

Refined ESVs for sediment COPECs identified in the SLERA and BERA Work Plan are provided in **Table 2**; the rationale for the selection of refined ESVs is presented in the sections below. In the absence of sufficient data to refine sediment ESVs, the conservative minimum ESV used in the SLERA will be retained. However, further literature review may be conducted to refine ESVs for these COPECs in the BERA Problem Formulation.

Inorganic COPECs

Refined sediment ESVs for metal COPECs will be using the consensus-based threshold effects concentrations (TEC) approach (MacDonald et al., 2000), as available. In the absence of consensus-based TECs, refined ESVs will be selected from sources in the following order of preference:

- USEPA Region 5 ESLs
- USEPA Region 3 Biological Technical Assistance Group (BTAG) Freshwater Sediment Screening Benchmarks
- Threshold Effect Levels (TELs) for *Hyalella azteca* (USEPA, 1996; Ingersoll et al., 1996)

The refined ESV for total cyanide of 0.1 mg/kg will be based on the USEPA Region 3 BTAG screening value, which was adopted from Persaud et al. (1993). The minimum ESV previously used in the SLERA (0.0001 mg/kg) was based on the USEPA Region 5 ESL for total cyanide, which also cited Persaud et al. (1993) as a source. However, USEPA Region 5 erroneously presented the Persaud et al. (1993) value as 0.0001 mg/kg. Therefore, the correct value of 0.1 mg/kg from Persaud et al. (1993) will be used as the refined ESV for total cyanide in sediment.

Inorganic COPECs in sediment will also be evaluated relative to site-specific background data collected as part of the Phase II Site Characterization to further refine sediment COPECs in the BERA (Roux Associates, 2018c). As stated in the BERA Work Plan and consistent with USEPA (2001), representative background concentrations calculated from Phase II Site Characterization background data will be used as the refined ESV to evaluate the need for further consideration of essential nutrients in the BERA (**Table 2**).

Organic COPECs

Refined ESVs for organic COPECs in sediment will be based primarily on EqP-based criteria protective of direct contact toxicity pathways to benthic organisms. Refined ESVs for PAHs in sediment will be based on USEPA *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures* (USEPA, 2003d). Exposure to PAH mixtures in sediment will be evaluated for potential additive narcotic effects to benthic organisms based on the sum of equilibrium partitioning sediment benchmark toxic units (∑ESBTUs) calculated from individual PAH compounds:

$$\sum ESBTU_{FCV,Total} = \sum_{i=1}^{16} \frac{C_{oc,PAHi}}{C_{oc,PAHi,FCVi}} \times UF$$

where:

$\sum ESBTU_{FCV,Total}$	= Sum of ESBTUs for the PAH mixture based on 34 PAH compounds (unitless)
$C_{oc,PAHi}$	= Organic carbon normalized concentration of PAH *i* ($\mu g/g_{oc}$)
$C_{oc,PAHi,FCVi}$	= Organic carbon normalized critical concentration of PAH *i* based on the final chronic value (FCV; $\mu g/g_{oc}$)
UF	= Uncertainty factor to estimate the toxicity of total PAHs (based on 34 PAHs – 18 parent and 16 alkylated compounds)

∑ESBTU values less than or equal to 1.0 are considered acceptable for the protection of benthic invertebrate receptors; values exceeding 1.0 indicate a potential for narcotic effects in benthic receptors (USEPA, 2003d).

Sediment samples collected in the Phase I Site Characterization were analyzed for 16 of the 34 PAH compounds included in the USEPA ESB model[1]; therefore, for the Phase I data, a site-specific uncertainty

[1] Analyzed PAH compounds include: naphthalene, acenaphthylene, acenaphthene, fluorene, anthracene, phenanthrene, pyrene, fluoranthene, benz(a)anthracene, chrysene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(g,h,i)perylene, indeno(1,2,3-cd)pyrene, dibenzo(a,h)anthracene.

factor (UF) or site-specific relationship will be applied to the ∑ESBTU values calculated based on 16 compounds ($\sum ESBTU_{FCV,16}$) to estimate $\sum ESBTU_{FCV,Total}$. Sediment samples collected from select stations in the Phase II Site Characterization sampling will be analyzed for the 34 PAH compounds included in the USEPA ESB model; therefore, $\sum ESBTU_{FCV,Total}$ values will be calculated directly based on the concentrations of the 34 PAH compounds measured in these samples.

Site-specific relationships will be developed to estimate the potential toxicity of unmeasured PAHs in the ∑ESBTU calculation in samples where only 16 compounds were analyzed. Site-specific relationships will be evaluated between ∑ESBTU values calculated based on 34 compounds ($\sum ESBTU_{FCV,34} = \sum ESBTU_{FCV,Total}$) and 16 compounds ($\sum ESBTU_{FCV,16}$). Site-specific ratios of $\sum ESBTU_{FCV,34}$:$\sum ESBTU_{FCV,16}$ may be developed as UFs to account for unmeasured PAHs in samples analyzed for 16 PAH compounds. The development of UFs based on $\sum ESBTU_{FCV,34}$:$\sum ESBTU_{FCV,16}$ ratios is consistent with the estimation of UFs in USEPA (2003d); however, the use of site-specific ratios provides more relevant UFs for PAH mixtures at the Site. Alternatively, $\sum ESBTU_{FCV,Total}$ values may be estimated using site-specific linear regression models developed based on paired $\sum ESBTU_{FCV,16}$ and $\sum ESBTU_{FCV,34}$ values at stations where 34 PAH compounds are analyzed, provided a significant linear relationship can be derived. The use of site-specific relationships to predict $\sum ESBTU_{FCV,34}$ from $\sum ESBTU_{FCV,16}$ in historical samples is intended to reduce the uncertainty of applying generic UFs provided in USEPA (2003d) to account for the potential toxicity of unmeasured PAHs in the ∑ESBTU calculation.

The availability of ESVs for non-PAH semi-volatile organic compound (SVOC) COPECs is limited (**Table 2**). An EqP-based sediment benchmark provided in USEPA (2008c) will be used as a refined ESV for dibenzofuran. An EqP-based sediment benchmark for 4-methylphenol adopted by USEPA Region 5 as an ESL will be used as a refined ESV for 3- & 4-methylphenol. The EqP-based sediment benchmark for 4-methylphenol was lower than the USEPA Region 5 EqP-based sediment benchmark for 3-methylphenol; therefore, the refined ESV will be conservative based on the assumption that the 3- & 4-methylphenol concentration consists entirely of 4-methylphenol.

ESVs were not identified for other non-PAH SVOC COPECs. However, refined ESVs may be calculated using an EqP model if the review of the combined Phase I and Phase II Site Characterization data indicates frequent detection of these non-PAH SVOC COPECs (greater than 5 percent of samples[2]). For select nonionic organic constituents, refined ESVs will be based on sediment quality benchmarks (SQBs) calculated using an EqP model (USEPA, 2008c). SQBs represent concentrations in bulk sediment that, at equilibrium, would result in partitioning to sediment pore water at concentrations equivalent to NOEC water quality benchmarks (WQB_{NOEC}) based on constituent-specific organic carbon-water partitioning coefficients (K_{oc}):

$$SQB_{NOEC} = (f_{oc} \times K_{oc} \times WQB_{NOEC})$$

where:

[2] USEPA (2001) provides for the refinement of COPECs based on frequency and magnitude of detection. Assuming the Phase I and Phase II Site Characterization data provide adequate coverage, a frequency of detection of less than 5 percent in site datasets will be used to refine COPECs from further consideration in the BERA, as proposed in the BERA WP (EHS Support, 2018a).

SQB_{NOEC}	= Sediment quality benchmark based on NOEC aqueous toxicity data (µg/kg dry weight sediment)
f_{oc}	= fraction of organic carbon (kg OC/kg sediment)
K_{oc}	= organic carbon-water partitioning coefficient (L/kg)
WQB_{NOEC}	= water quality benchmark based on a chronic NOEC (µg/L)

For select nonionic organic constituents, refined ESVs will be based on SQBs calculated assuming minimum f_{oc} within the exposure area and WQB_{NOEC} values based on surface water quality benchmarks derived for the general protection of aquatic life. Exposure estimates for COPECs exceeding SQBs calculated assuming minimum f_{oc} within the exposure area will be further evaluated based on sample-specific f_{oc} in the BERA exposure assessment. In the absence of sufficient data to refine sediment ESVs based on EqP approaches, the conservative minimum ESV used in the SLERA will be retained.

Refined Surface Water ESVs

Refined ESVs for surface water will be primarily based on USEPA National Recommended Water Quality Criteria (NRWQC) or MDEQ chronic surface water quality for the protection of aquatic life (**Table 3**). Chronic aquatic life surface water criteria are derived for the protection of 95 percent of aquatic species. Therefore, these criteria are considered adequately protective to identify COPEC concentrations in surface water that have the potential to result in adverse ecological effects and warrant additional evaluation in the BERA.

Inorganic COPECs

Refined surface water ESVs for metal COPECs will be based on USEPA NRWQC or MDEQ chronic surface water quality for the protection of aquatic life, where applicable. Refined surface water ESVs for metal COPECs will be applied to the sample result fraction (total versus dissolved) that corresponds to the aqueous toxicity endpoint (total versus dissolved) used as the basis for chronic aquatic life surface water criteria.

For USEPA NRWQC, chronic surface water quality criteria for many metals are based on exposure to the dissolved fraction (**Table 3**). Refined ESVs for these metals will be compared to metals concentrations in surface water samples filtered through a 0.45-µm pore size filter, which operationally defines the dissolved COPEC fraction. USEPA NRWQC for cadmium, lead, nickel, and zinc are adjusted for total hardness (as $CaCO_3$) using the equations provided in **Table 3**. USEPA NRWQC for copper and aluminum are based on models developed to characterize the bioavailable forms of these metals in surface water based on water quality parameters. The NRWQC for copper is based on the Biotic Ligand Model (BLM), which accounts for organic compounds and inorganic ligands in surface water that are known to complex with copper and affect bioavailability and toxicity (USEPA, 2007b). For aluminum, the refined ESV will be based on draft USEPA aquatic life ambient water quality criteria developed using multiple linear regression models to characterize aluminum bioavailability based on pH, hardness, and dissolved organic carbon (DOC; USEPA, 2017).

MDEQ Aquatic Life Standards (DEQ-7) for metals are based on the total (unfiltered) fraction, except for aluminum. MDEQ criteria for cadmium, copper, lead, nickel, and zinc will be adjusted for total hardness (as $CaCO_3$) using the equations provided in **Table 3**.

Refined ESVs for metals will be based on NRWQC or MDEQ criteria applicable to the sample result fraction (total versus dissolved). If the maximum EPC exceeds the applicable criterion for the corresponding fraction, the metal COPEC will be further evaluated in the BERA.

For metals that lack USEPA NRWQC or MDEQ surface water quality criteria (beryllium and manganese), refined ESVs will be based on lowest chronic values reported for all organisms (fish, daphnids, non-daphnid invertebrates, and aquatic plants) in Suter and Tsao (1996). A revised surface water ESV was not identified for barium; therefore, the minimum ESV used in the SLERA will be used as the basis for further evaluation in the BERA.

ESVs for cyanide and fluoride will be based on minimum ESVs used in the SLERA. The NRWQC criterion for cyanide is based on free cyanide analysis, which represents the concentration of the cyanide ion (CN^-) and hydrogen cyanide (HCN). The MDEQ surface water quality criterion for cyanide is based on total cyanide analysis. If the maximum EPC for free cyanide or total cyanide analyses exceed the applicable criterion, cyanide exposure in surface water will be further evaluated in the BERA.

Inorganic COPECs in surface water will also be evaluated relative to site-specific background data collected as part of the Phase II Site Characterization to further refine surface water COPECs in the BERA.

Organic COPECs

Select PAH compounds were identified as surface water COPECs based on the screening of Phase I Site Characterization and additional COPECs identified in the BERA WP based on detected constituents lacking ESVs. As indicated in **Table 3**, revised ESVs for select PAH compounds will be based on lowest chronic values reported for all organisms (fish, daphnids, non-daphnid invertebrates, and aquatic plants) in Suter and Tsao (1996). If individual PAH compounds exceed revised ESVs, further evaluation of the potential toxicity of PAH mixtures to aquatic organisms will be further evaluated in the BERA.

Subject: **Technical Memorandum: Proposed Wildlife Exposure Modeling Approach to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site**
Former Columbia Falls Aluminum Company Aluminum Reduction Facility
Columbia Falls, Montana

On behalf of Columbia Falls Aluminum Company, LLC (CFAC), Roux Environmental Engineering and Geology, D.P.C. (Roux) and EHS Support, LLC prepared the attached Technical Memorandum for Proposed Wildlife Exposure Modeling Approach to Support the Baseline Ecological Risk Assessment (BERA) for the CFAC Superfund Site in Columbia Falls, Montana. This memorandum has been prepared as part of the ongoing Remedial Investigation/Feasibility Study (RI/FS) being conducted pursuant to the Administrative Settlement Agreement and Order on Consent (AOC) dated November 30, 2015 between CFAC and the United States Environmental Protection Agency (USEPA) (CERCLA Docket No. 08-2016-0002).

Should there be any questions or comments on this submission, please do not hesitate to contact me at (631) 230-2300.

Sincerely,

Laura Jensen

Re: *Technical Memorandum: Proposed Wildlife Exposure Modeling Approach to Support the Baseline Ecological Risk Assessment at the Columbia Falls Superfund Site*
Former Columbia Falls Aluminum Company Aluminum Reduction Facility
Columbia Falls, Montana

Introduction

This technical memorandum describes the approach for estimating dietary exposure to terrestrial and semi-aquatic wildlife in the Baseline Ecological Risk Assessment (BERA) for the Columbia Falls Aluminum Company (CFAC) Superfund Site in Columbia Falls, Montana. The technical memorandum was prepared as an interim deliverable to supplement the general risk assessment framework provided in the *Baseline Ecological Risk Assessment Work Plan* (BERA WP) submitted to the United States Environmental Protection Agency (USEPA) and Montana Department of Environmental Quality (MDEQ) in November 2017 and revised in May 2018 (EHS Support, 2018).

The technical memorandum presents the modeling approach, preliminary exposure parameters, bioaccumulation relationships, and toxicity reference values (TRVs) that are proposed to evaluate dietary pathways to terrestrial and semi-aquatic wildlife receptors that may be exposed to bioaccumulative constituents of potential ecological concern (COPECs) at the Site. Bioaccumulation relationships and TRVs are proposed for potentially bioaccumulative COPECs identified in the *Screening Level Ecological Risk Assessment* (SLERA) conducted based on Phase I Site Characterization data (Roux Associates, 2017). Further identification of potentially bioaccumulative COPECs will be conducted based on a re-screening of the Phase I Site Characterization data with additional data being collected in accordance with the Phase II Site Characterization Sampling and Analysis Plan (Roux Associates, 2018). In addition, further evaluation of the appropriateness of exposure assumptions and model parameters presented in this technical memorandum may be warranted in the BERA to reduce uncertainty in dietary exposure estimates used to characterize risk to wildlife through dietary pathways. The BERA Report will include an appendix that provides documentation and justification for the exposure parameters and model assumptions used in dietary exposure models for the Site.

The following sections describe the identification of preliminary bioaccumulative COPECs to evaluate via dietary exposure pathways, the dietary exposure modeling approach and parameters, and the preliminary selection of wildlife TRVs.

Identification of Bioaccumulative COPECs

COPECs identified in the SLERA and BERA WP based on the preliminary analysis of Phase I Site Characterization data (Roux Associates, 2017) were evaluated to identify potentially bioaccumulative constituents for dietary exposure modeling in the BERA. COPECs were conservatively identified in the SLERA based on comparisons of maximum concentrations in the Phase I Site Characterization datasets to minimum ecological screening values (ESVs). In addition, the BERA WP identified additional COPECs based on detected constituents lacking ESVs. COPECs with the potential to bioaccumulate were identified for dietary exposure modeling in the BERA based on satisfaction of one or more of the following criteria:

1. Constituents identified as Persistent, Bioaccumulative, and Toxic Constituents as part of the USEPA Toxics Release Inventory (TRI) Program
2. Constituents identified as important bioaccumulative constituents in USEPA (2000)
3. Organic constituents with a log octanol-water partitioning coefficient (log K_{ow}) greater than 3.5 based on USEPA (2000)
4. Constituents with USEPA Ecological Soil Screening Levels (Eco-SSLs) derived for birds or mammals (USEPA, 2005a).

Table 1 presents a preliminary list of COPECs that will be included in dietary exposure modeling in the BERA based on the above criteria. The preliminary list of bioaccumulative COPECs presented in Table 1 will be re-evaluated based on the combined results of the Phase I and Phase II Site Characterization sampling. As indicated in the BERA WP, relevant exposure data from the Phase I and Phase II Site Characterization datasets will be re-screened to identify COPECs based on conservative comparisons of maximum concentrations to minimum ESVs. COPECs identified in the re-screening of the combined Phase I and Phase II datasets that have the potential to bioaccumulate based on one or more of the above criteria will be included in the dietary dose modeling presented in the BERA. Dietary exposure to these potentially bioaccumulative COPECs will be evaluated in a manner consistent with the approach described in this technical memorandum.

Dietary Exposure Modeling

The evaluation of potential exposure via direct and incidental ingestion pathways will be conducted based on a tiered approach in accordance with the USEPA guidance for conducting probabilistic ecological risk assessment (USEPA, 2001). The tiered approach will include the following ingestion models to quantitatively assess potential risks to representative wildlife receptors:

- Deterministic exposure modeling: Based on conventional single point estimates of exposure point concentrations (EPCs) and typical exposure parameters. Deterministic exposure models will be developed based using a tiered approach that incorporates preliminary and refined exposure estimates:
    - Preliminary exposure estimates: Screening-level exposure assumptions based on maximum EPCs and conservative exposure assumptions.

    - Refined exposure estimates: Refined exposure estimates using EPCs based on conservative estimates of the mean concentrations at the site, assuming random foraging throughout each exposure area and more realistic exposure assumptions.

  Further discussion of the assumptions supporting the preliminary and refined exposure estimates are provided in relevant sections within this technical memorandum.
- Probabilistic exposure modeling: If estimated doses based on refined deterministic modeling exceed doses associated with lowest-observed-adverse-effect levels (LOAELs), probabilistic models may be developed to estimate exposure based on the distributions of EPCs and exposure parameters to account for variability and/or uncertainty in model parameters.

The following sections describe the basic model structure, receptor-specific exposure factors, exposure variables, bioaccumulation relationships, and area use factors that will be used for dietary exposure modeling in the BERA.

Model Structure

The underlying algorithm of the dietary exposure model is the same for deterministic and probabilistic approaches. However, deterministic estimates use single, discrete values for model parameters (i.e., representative of a typical or a worst case), whereas probabilistic estimates use a distribution of values for model parameters to account for the inherent variability and/or uncertainty in the estimation of those parameters. Procedures for calculating probabilistic exposure estimates are consistent with USEPA (2001) guidance on probabilistic ecological risk assessments and USEPA (1997) guidance on Monte Carlo analyses. The following sections describe the model structure and the general procedures for deterministic and probabilistic modeling.

Deterministic Modeling Procedures

Deterministic exposure estimates will be based on comparisons of receptor-specific estimated daily doses (EDDs) calculated from simple dose rate models to TRVs. Dietary exposure estimates consider receptor-specific exposure factors, including typical dietary composition, and exposure variables that represent site-specific measurements of COPEC concentrations in exposure media. The general form of the dose rate model used to calculate EDDs is:

$$EDD = \frac{1}{BW}\sum_{i=1}^{N}\left(FIR_{dw} \times \sum_{j=1}^{M}\left(f_j \times C_j\right) + SIR_{dw} \times C_{sub} + WIR \times C_{sw}\right)_i \times AUF_i \qquad (1)$$

where:

N = Number of exposure areas within the typical receptor home range
M = Receptor-specific dietary items
BW = Receptor-specific body weight (kg)
FIR_{dw} = Receptor-specific daily food ingestion rate (kg/day, dry weight)
f_j = Proportion of dietary item *j* to total dietary composition
C_j = COPEC concentration in dietary item *j* (mg/kg tissue dry weight)
SIR_{dw} = Receptor-specific incidental substrate ingestion rate (kg/day, dry weight)
C_{sub} = COPEC concentration in substrate (mg COPEC/kg substrate, dry weight)
WIR = Receptor-specific daily drinking-water ingestion rate (Liters (L)/day)
C_{sw} = COPEC concentration in unfiltered surface water (mg COPEC/L)

AUF_i = Area use factor for a given exposure area and receptor

For receptors with foraging ranges that are smaller than a given exposure area, the EDD will be calculated based on EPCs derived from data collected within that exposure area. If the foraging range of a receptor is greater than an exposure area, the EDD will be calculated as the sum of area use factor (AUF)-weighted doses obtained from the exposure areas within the typical home range of the receptor. Further explanation regarding the calculation of AUFs is presented in the *Area Use Factors* section of this technical memorandum.

As stated in the BERA WP, dietary exposure to small home range receptors will also be evaluated based on point-by-point comparisons of measured COPEC concentrations in biologically relevant sampling intervals to estimated soil or sediment benchmark concentrations that are back-calculated from TRVs. Consistent with the approach used to calculate USEPA Eco-SSL values (USEPA, 2005a), the general exposure model presented in Equation 1 will be used to back-calculate soil or sediment benchmarks for each representative small home range receptor by setting the EDD equivalent to the TRV and solving for the C_{sub} value.

A modified version of the dietary exposure model presented in Equation 1 will be used to evaluate the potential additive exposure to dioxin/furan compounds in surface soil sampled within the Main Plant Area and adjacent areas. Additive exposure to dioxin/furan compounds will be evaluated using the toxicity equivalence methodology consistent with USEPA (2008a). The modified dietary exposure model will calculate an EDD for the 17 individual dioxin/furan compounds in each sample based on the general model presented above. The EDD for each compound will be multiplied by the compound-specific toxicity equivalence factor (TEF) for birds or mammals relative to the toxicity of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) to estimate the toxicity equivalence concentration (TEC) for each compound (Van den Berg et al., 2006; Van den Berg et al., 1998; USEPA, 2008a). TECs of the 17 dioxin/furan compounds will be summed to calculate an overall TEC:

$$TEC = \sum_{n=1}^{k} EDD_n \times TEF_n \qquad (2)$$

where:
TEC = Toxicity equivalence concentration
EDD_n = Estimated daily dose calculated for dioxin-like chemical n
TEF_n = Toxicity equivalence factor for dioxin-like chemical n
k = Number of toxic dioxin-like chemicals in the mixture

The TEC will be evaluated relative to dietary TRVs for 2,3,7,8-TCDD derived for birds and mammals.

Probabilistic Modeling Procedures

Procedures for calculating probabilistic exposure estimates will be consistent with USEPA (2001) guidance on probabilistic ecological risk assessments and USEPA (1997) guidance on Monte Carlo analyses. As warranted based on the outcome of deterministic exposure estimates, Monte Carlo simulations may be conducted using the statistical computing and graphics language R (R Core Team, 2013) to estimate the EDD and the average estimated daily dose (AEDD) distributions for each receptor based on the following procedures.

To estimate the EDD distribution for a receptor:

1. R will be used to randomly select a body weight (BW) from its literature-derived distribution and to calculate the corresponding food ingestion rate (dry weight) (FIR_{dw}), incidental substrate ingestion rate (dry weight) (SIR_{dw}), and drinking water ingestion rate (WIR).
2. f_i will be selected based on dietary composition.
3. C_i and C_{sub} will be randomly selected from their corresponding distributions from site-specific concentrations measured during the Phase I and Phase II Site Characterization sampling.
4. EDD will be calculated using Equation (1) above.
5. Steps #1 to #4 will be repeated a pre-set number of times to estimate the EDD distribution; the number of iterations will be pre-set at 10,000 based on convergence criteria provide in Sample et al. (1996a).

To estimate the average estimated daily dose (AEDD) distribution for a receptor:

1. The Bootstrapping Method will be used to randomly select N number of EDD from the EDD distribution above, where N = Number of days/year the receptor is exposed within site exposure areas.
2. AEDD, defined as the arithmetic mean of the selected EDDs, will be calculated.
3. Steps #1 and #2 will be repeated a pre-set number of times to estimate the AEDD distribution; the number of iterations will be pre-set at 10,000 based on convergence criteria provide in Sample et al. (1996a).

The following section presents the basis for selecting receptors of concern and model parameters used in deterministic and probabilistic dietary exposure modeling.

Receptors of Concern

Ecological exposure areas identified in the BERA WP may support multiple terrestrial and semi-aquatic wildlife receptors of concern (EHS Support, 2018). As indicated in the BERA WP, exposure to avian and mammalian wildlife receptors will be evaluated based on dietary exposure pathways using the approach presented in this technical memorandum. Exposure to other ecological receptors of concern, including fish, reptiles, and amphibians, will be evaluated based on direct contact exposure pathways in the BERA (EHS Support, 2018).

Several surrogate species were identified in the BERA WP as representative species to evaluate exposure to mammalian and avian receptors based on feeding guild using dietary exposure models. Representative terrestrial species for each receptor group based on feeding guild include:

Receptor Group	Scientific Name	Common Name
Mammalian Fauna		
Herbivorous mammal	*Microtus pennsylvanicus*	Meadow Vole
Insectivorous mammal	*Blarina brevicauda*	Northern Short-tailed Shrew
Carnivorous mammal	*Mustela frenata*	Long-tailed Weasel
Avian Fauna		
Herbivorous bird	*Zenaida macroura*	Mourning Dove
Invertivorous bird	*Scolopax minor*	Woodcock
Carnivorous bird	*Buteo jamaicensis*	Red-tailed Hawk

Representative semi-aquatic species for each receptor group based on feeding guild include:

Receptor Group	Scientific Name	Common Name
Mammalian Fauna		
Piscivorous mammal	*Mustela vison*	Mink
Avian Fauna		
Invertivorous bird	*Cinclus mexicanus*	American Dipper
Piscivorous bird	*Megaceryle alcyon*	Belted Kingfisher

In addition to the mammalian and avian receptors representing feeding guilds expected to be present at the site, potential dietary exposure to four federally threatened (or proposed threatened) species identified by the United States Fish and Wildlife Service Information for Planning and Consultation[1] (USFWS IPaC) will also be evaluated (EHS Support, 2018):

Scientific Name	Common Name	Status	Potential Exposure Area – General Habitat
Mammals			
Lynx canadensis	Canada Lynx	Threatened	Terrestrial – Boreal spruce-fir forest habitat
Ursus arctos horribilis	Grizzly Bear	Threatened	Terrestrial – Relatively undisturbed mountainous habitat
Gulo gulo luscus	North American Wolverine	Proposed Threatened	Terrestrial – High elevation habitat near the tree-line
Birds			
Coccyzus americanus	Yellow-billed Cuckoo	Threatened	Terrestrial – Dense, cottonwood-dominated forests canopies

[1] Accessed at: https://ecos.fws.gov/ipac

The following sections present receptor-specific exposure factors selected to estimate dietary doses to wildlife receptors of concern.

Receptor-Specific Exposure Factors

Receptor-specific exposure factors were identified to estimate exposure and area use for identified wildlife receptors of concern evaluated in dietary exposure models. Receptor-specific exposure factors used in the dietary exposure models include:

- BW
- FIR_{dw}
- SIR_{dw}
- WIR
- Dietary composition, proportion of dietary item *j* to total diet (f_j)
- AUF

Receptor-specific exposure parameters will be derived from general literature sources and compilations of exposure factors developed to support dietary exposure modeling (e.g., USEPA, 1993; USEPA, 2007a; USCHPPM, 2004; Sample and Suter, 1994).

Deterministic exposure modeling uses exposure factors that are representative of typical or average (e.g., mean parameter) exposure conditions. Probabilistic exposure modeling evaluates a range of potential exposure factors to capture the individual- and population-level variation in exposure factors that are likely to occur within exposure areas. A summary of exposure factors that will be used in the deterministic exposure model is presented in **Table 2**. The approach for selecting exposure factors for dietary exposure models is summarized below.

Body Weight

In deterministic exposure models, representative body weights will be estimated as arithmetic mean values of adult body weights reported in the literature or midpoints of the range of body weights when arithmetic mean values are not available (**Table 2**). When body weights are available for both sexes, the more conservative (lower) estimate of the average body weight will be selected. Minimum body weights were identified from the available literature as conservative body weight estimates for special status species, including Canada lynx, grizzly bear, and North American wolverine (**Table 2**).

For probabilistic exposure estimates, distributions of potential body weights of adult receptors will be estimated using R based on available arithmetic mean (μ) and standard deviation (σ) of body weights reported in the literature for the selected receptors (**Table 2**). Normal distributions of potential body weights will be assumed for each receptor. Estimated distributions of potential body weights will be truncated to the range of body weights reported in the literature to avoid unrealistic estimates of receptor body weight (i.e., the distribution of potential body weights will not include values that are greater than or less than the range of body weights reported in the literature).

Food Ingestion Rate

Food ingestion rates FIR_{dw} will be estimated based on receptor-specific BW values using appropriate empirical allometric (scaling) relationships developed by Nagy (2001). Nagy (2001) derived allometric relationships for various avian and mammalian feeding groups based on taxon, habitat, and diet. For each wildlife receptor, the most appropriate allometric equation from Nagy (2001) will be used to estimate dry weight food ingestion FIR_{dw} as a function of BW (**Table 2**):

$$FIR_{dw} = a \times BW^{b} \quad (3)$$

where:

FIR_{dw} = Dry weight food ingestion rate (kg dry weight/day)
BW = Receptor-specific body weight (kg)
a and b = Parameters whose values are specific to an allometric equation (see **Table 2**)

In deterministic exposure models, the receptor-specific FIR_{dw} estimated from the appropriate allometric relationship will be used based on average body weight in the point estimate calculation of the EDD. For probabilistic exposure models, distributions of FIR_{dw} will be developed based on allometric relationships using randomly selected body weights from the body weight distribution described in the preceding section. The randomly selected body weights will be used to estimate corresponding FIR_{dw} values using the appropriate form of Equation 3 for the receptor of concern. The resulting distribution of FIR_{dw} will be representative of the range of feeding rates that may be observed within a given receptor population as a function of the potential range of body weights of individuals within the population.

Potential distributions of FIR_{dw} values will not be developed directly from literature-reported values for the following reasons:

- Literature-derived FIRs (primarily mean values) are insufficient to generate robust distributions.
- It is inappropriate to evaluate FIR_{dw} independent of BW; if BW and FIR_{dw} are independent in a probabilistic simulation, a receptor at the lower end of the BW distribution may be unrealistically paired with a FIR_{dw} value at the higher end of the FIR_{dw} distribution.

Incidental Substrate Ingestion Rate

Exposure models account for the dietary intake of soil or sediment (substrate) that may be ingested incidentally because of the feeding behavior of select receptors or indirectly through the ingestion of prey. Incidental substrate ingestion rates (SIR_{dw}) will be estimated based on the average incidental substrate ingestion as a percentage of dry food intake based on FIR_{dw} values derived by Nagy (2001) using the approach described in the preceding section. SIR_{dw} will be expressed as a proportion of the dry food ingestion rate, as follows:

$$SIR = FIR_{dw} \times \left(\frac{Ps}{100}\right) \quad (4)$$

where:

SIR_{dw} = Substrate ingestion rate (kg dry weight/day)
FIR_{dw} = Dry weight food ingestion rate (kg dry weight/day)
P_s = Percentage of dry food intake ingested as substrate

As summarized in **Table 2**, average substrate ingestion, as a percentage of dry food intake, was identified for each receptor of concern based on literature sources. For receptors included in the derivation of Eco-SSLs, the average percentage of dry food intake was obtained from USEPA (2007a). For primarily piscivorous wildlife (mink and belted kingfisher), incidental substrate ingestion was assumed to be negligible, consistent with Sample and Suter (1994). For carnivorous mammals, including Canada lynx, grizzly bear, and North American wolverine, incidental substrate ingestion was assumed to not exceed the average incidental ingestion rate for the red fox reported in Beyer et al. (1994). No incidental substrate ingestion data were identified for the American dipper; therefore, a nominal incidental substrate ingestion rate of 1 percent of dry intake was assumed for American dipper (**Table 2**). However, based on the habitat preference of American dipper for fast-moving, clear streams with sand, pebble, or rocky stream bottoms, the assumption of 1 percent incidental substrate ingestion is likely conservative. Further evaluation of this assumption may be warranted in the BERA pending the potential influence of incidental sediment exposure in the risk characterization for American dipper.

For the deterministic exposure model, the receptor-specific SIR_{dw} will be estimated as a single point estimate based on the dry weight FIR_{dw} calculated using average BW and the average percentage of dry food intake as incidental substrate ingestion (**Table 2**).

For probabilistic exposure models, a distribution of potential SIRs will be developed for each receptor based on the distribution of FIR_{dw} described in the previous section. The distribution of SIRs will be developed based on randomly selected BW values used to develop the distribution of FIR_{dw}. For each randomly selected body weight, a corresponding SIR_{dw} will be calculated using the dry weight FIR_{dw} and the average percentage of dry food intake as incidental substrate ingestion. The receptor-specific distribution of SIRs is representative of the range of rates that may be observed within a given receptor population as a function of the potential range of body weights and corresponding food ingestion rates of individuals within that population.

Drinking Water Ingestion Rate

Drinking-water ingestion rates (WIRs) will also be derived based on an allometric relationships to body weight. For birds, Calder and Braun (1983) developed an equation for drinking-water ingestion based on a dataset representing 21 bird species with a body weights ranging from 0.011 to 3.15 kg, which encompasses the range of average avian body weights included in the exposure modeling for the Site (**Table 2**). WIRs for avian receptors will be estimated based on body weight as follows:

$$WIR_{avian} = 0.059 \times BW^{0.67} \quad (5)$$

where:
WIR_{avian} = Avian drinking water ingestion rate (L/day)
BW = Receptor body weight (kg)

Drinking-water ingestion rates for mammalian receptors ($WIR_{mammalian}$) will be estimated based on an allometric relationship to body weight using an analogous equation from Calder and Braun (1983):

$$WIR_{mammalian} = 0.099 \times BW^{0.90} \quad (6)$$

where:
$WIR_{mammalian}$ = Mammalian drinking-water ingestion rate (L/day)

BW = Receptor body weight (kg)

Like other ingestion rates based on allometric relationships (e.g., FIR_{dw} and SIR_{dw}), estimates of WIR in deterministic exposure models will be based on arithmetic mean values of adult body weights reported in the literature or minimum body weights when arithmetic mean values are not available (**Table 2**). For probabilistic exposure models, WIRs will be calculated from randomly selected body weights used to develop the receptor-specific distributions of body weight, FIR_{dw}, and SIR_{dw}. Estimated WIRs calculated for each randomly selected body weight form a receptor-specific distribution that is representative of the range of drinking water rates that may be observed within a given receptor population, as a function of the potential range of body weights of individuals within that population.

Dietary Preference

Dietary models are developed to evaluate exposure to various trophic categories of wildlife based on typical feeding behaviors. Receptors select dietary items based on species-specific foraging strategies and behaviors, which are also influenced by the availability and abundance of dietary items within an exposure area. The relative compositions of prey items in the diets of wildlife receptors of concern will be estimated based on dietary studies obtained from the literature and summarized in compilations of exposure factors developed to support dietary exposure modeling (USEPA, 1993; USEPA, 2007a; USCHPPM, 2004; Sample and Suter, 1994).

Estimates of dietary composition in deterministic exposure models will be simplified initially to represent the predominant dietary items and/or more conservative exposure scenarios based on literature. A summary of the preliminary dietary compositions for the various receptors that will be evaluated in deterministic exposure models is presented in **Table 2**.

Probabilistic exposure estimates may consider the probability of a receptor selecting and ingesting a certain dietary item during foraging. USEPA (2003a) developed an algorithm to construct a unique and randomly selected diet for receptors based on a dietary matrix. A similar approach may be used to account for potential variability in dietary composition if probabilistic dietary exposure modeling is conducted in the BERA. If this approach is warranted, further documentation will be presented in the appendix describing the wildlife modeling procedures in the BERA Report.

Exposure Point Concentrations

Exposure variables refer to site-specific measurements, namely COPEC concentrations estimated in exposure media. The following sections describe the approach for defining EPCs for deterministic and probabilistic exposure modeling.

Deterministic Exposure Point Concentrations

EPCs to evaluate wildlife exposure in deterministic models in the BERA will be estimated for each exposure area using data collected as part of the Phase I and Phase II Site Characterization. EPCs will be calculated to represent a range of exposure scenarios:

- Maximum EPC: Represents a maximum exposure scenario based on the maximum measured concentration in each exposure area.

- Refined EPC: Represents the likely exposure to a conservative estimate of the mean concentrations at the site, assuming random foraging throughout each exposure area.

Refined EPCs for evaluating wildlife ingestion pathways will be calculated based on upper confidence limit of the mean (UCL_{mean}) COPEC concentrations. UCL_{mean} values represent a conservative estimate of average exposure conditions for a receptor foraging randomly over an exposure area. UCL_{mean} concentrations will be calculated using USEPA ProUCL software (version 5.1 or later) and the statistical approach will be consistent with USEPA ProUCL Version 5.1 Technical Guidance (USEPA, 2015). The UCL_{mean} calculation recommended in ProUCL will typically be used as the refined EPC in the risk estimate. However, ProUCL occasionally recommends the 97.5 or 99% UCL on the arithmetic mean estimated by the Chebyshev method when other methods (e.g., Hall's or bootstrap-t UCL with outliers) result in a 95% UCL that exceeds the maximum value. In these cases, the data will be reviewed, and the 95% UCL estimated by the Chebyshev method may be selected as the EPC in those situations to be consistent with the intent of the reasonable maximum exposure paradigm as defined by EPA (1989; 2002). This approach is also consistent with ProUCL technical guidance (EPA, 2015). EPCs for large-range receptors that include multiple exposure areas (up to and including all exposure areas within the Site), will be calculated using a sum of spatially-weighted estimated daily doses (EDDs) from each of the exposure areas where the receptor may forage. For example, if the size of the Main Plant Area is 70% of the receptor home range, and other sampled areas outside the Main Plant Area (but within the home range of the species) includes an additional 20% (with off-site areas comprising the remaining 10% of the home range), then the total EDD will be equal to (0.7 x Main Plant Area EDD) + (0.2 x non-Main Plant Area EDD) for each chemical.

In addition to UCL_{mean} EPCs, exposure will also be evaluated on a point-by-point basis for wildlife receptors with small home ranges (e.g., meadow vole, short-tailed shrew). Point-by-point comparisons will be conducted for COPECs with maximum EPCs resulting in EDDs that exceed TRV_{Low} doses. The evaluation of potential exposure on a point-by-point basis will support a spatial evaluation of areas where small home range receptors may be exposed to concentrations in soil that may result in adverse effects.

EPCs for small home-range receptors will also be determined for incremental soil methodology (ISM) samples collected in the 43 decision units (DU) within the Operational Soil Area (Roux Associates, 2015). The DUs are approximately 1 acre in size. As indicated in the Phase II Site Characterization Sampling and Analysis Plan (Roux Associates, 2018), replicate ISM samples (r=3) will be collected from four DUs within the Operational Soil Area (approximately ten percent of the total number of DUs in the Operational Soil Area). UCL_{mean} concentrations to estimate EPCs for the DUs with replicate ISM samples will be calculated using the Chebyshev UCL or Student's t UCL methods using the 95% UCL Calculator developed by the ITRC (ITRC, 2012). Given that DUs in the Operational Soil Area have a similar conceptual site model, including similar soil type, site use/history, and expected contaminant types, ISM replicates from the four DUs will be used to provide an estimate of ISM sample variability within a DU. Estimates of ISM sample variability will be extrapolated to similar DUs without replicate ISM samples (similar to how laboratories use batch replicates for determining lab analysis precision). The extrapolation of estimated variability measured in DUs with ISM replication will be conducted in accordance with the guidance

provided in ITRC (2012) based on an evaluation of ISM mean and variance estimates, including relative standard deviation (RSD)[2] and standard deviation, from the DUs with ISM replication.

The Operational Soil Area where the ISM sample grids are located represents a sub-area that overlaps previously established ecological exposure areas, specifically the Central Landfill Area and the Main Plant Area. Soil grab samples were also collected within the ISM sampling grids during Phase I and Phase II. Due to different underlying statistical properties, it is not appropriate to combine data derived from ISM and grab samples to calculate statistical parameters (e.g., UCL_{mean} EPCs for large-range receptors). The collection of grab samples was performed across the entire Site (including the Operational Soil Area) to fully characterize potential risk to ecological receptors. The ISM samples were only collected in a sub-area of the facility where contamination was suspected, but the locations of specific source areas and exposure pathways were not known. Therefore, data from grab samples that are nested within the ISM grids will be included in the Site-wide database that will be used to calculate EPCs for large ranging receptors that may forage in multiple exposure areas. The ISM soil data collected within the Operational Area will not be evaluated for large-range receptors and will only be evaluated in the BERA as focused areas of exposure for small ranging and sessile ecological receptors. ISM results (i.e., the concentrations resulting from the single replicate, or from the UCL_{mean} calculation performed on the DUs with triplicate samples) will be evaluated for each grid based on point-by-point comparisons with ecological benchmarks to evaluate soil exposure to plants, soil invertebrates, and wildlife receptors with foraging ranges less than the size (approximately one acre) of the ISM DUs. Results from grab samples that are appropriate for use in the BERA and that overlap the Operational Area ISM sample grid will also be included (along with all other grab samples within the ecologically relevant soil depth interval across the Site) in the point-by-point evaluation for small range and sessile ecological receptors.

The following sections discuss media-specific approaches for data compilation and pre-processing to support the estimation of EPCs.

Soil

For receptors that receive a majority of their soil exposure at the surface, only data from the surficial soil sampling interval (0 to 0.5 feet below ground surface [ft bgs]. For receptors whose life history patterns indicate the potential for regular exposure to deeper soil (e.g., the sort-tailed shrew, meadow vole, long-tailed weasel, and North American wolverine), dietary ingestion pathways associated with soils will be based on depth-weighted average concentrations of sampling intervals collected from 0-0.5 feet below ground surface (ft bgs) and 0.5-2.0 ft bgs to provide a representative EPC for each soil boring station. Depth-weighted average concentrations for the combined 0-2 ft bgs exposure interval will be calculated as follows:

$$C_{soil,0-2ft} = C_{soil,0-0.5ft} \times \frac{0.5ft}{2ft} + C_{soil,0.5-2ft} \times \frac{1.5ft}{2ft} \quad (7)$$

where:

$C_{soil,0\text{-}2\,ft}$ = Concentration in combined exposure interval starting from 0 to 2 ft bgs
$C_{soil,0\text{-}0.5\,ft}$ = Concentration in sampling interval starting from 0 to 0.5 ft bgs

[2] Relative standard deviation (RSD) is calculated as the standard deviation divided by the arithmetic mean. RSD is also referred to as the coefficient of variation (CV).

$C_{soil,0.5\text{-}2\ ft}$ = Concentration in sampling interval starting from 0.5 to 2 ft bgs

As indicated in the BERA WP, sediment data from the 0 to 0.5 ft bgs sampling interval will be included in soil EPC calculations for transitional exposure areas that may be seasonally dry and provide habitat for terrestrial receptors. As described in the BERA WP, transitional exposure areas include (EHS Support, 2018):

- North Percolation Pond Area
- South Percolation Pond Area
- Cedar Creek Reservoir Overflow Ditch
- Northern Surface Water Feature

Sediment

EPCs for sediment in aquatic exposure areas will be calculated based on surficial samples collected from the 0 to 0.5 ft bgs (nominal) sampling interval. Preliminary EPCs will be based on the maximum measured concentration within an exposure area to represent the most conservative exposure scenario. Refined EPCs will include a conservative estimate of the central tendency of exposure (e.g., UCL_{mean} concentration) to reflect the average dose that a receptor may experience while foraging randomly within an exposure area.

As indicated in the BERA WP, surficial soil data from the 0 to 0.5 ft bgs sampling interval will be included in sediment EPC calculations for transitional exposure areas that may be seasonally inundated and provide temporary aquatic habitat, in addition to terrestrial habitat. As described in the BERA WP, transitional exposure areas include (EHS Support, 2018):

- North Percolation Pond Area
- South Percolation Pond Area
- Cedar Creek Reservoir Overflow Ditch
- Northern Surface Water Feature

Surface Water

Relevant surface water sources that will be used as drinking water sources in the dietary exposure models for small-ranging (S) and long-ranging (L) terrestrial wildlife receptors are summarized below by terrestrial exposure area:

Exposure Area	Surface Water Source					
	Cedar Creek	Cedar Creek Resv. Overflow	North Percolation Ponds	South Percolation Ponds	Flathead River	Northern Surface Water Feature
Eastern Undeveloped Area	L	S,L	L	L	L	L
North-Central Undeveloped Area	L	S,L	S,L	L	L	S,L
Western Undeveloped Area	S,L	L	L	L	L	L
Central Landfill Area	L	S,L	S,L	L	L	L
Industrial Landfill Area	L	S,L	L	L	L	S,L

Notes:
S, Small-ranging receptors
L, Long-ranging receptors

For long-ranging receptors, potential drinking water sources will include an estimate of average exposure point concentrations (e.g., UCL_{mean}) from multiple surface water features that may be encountered while foraging. For receptors with small home ranges, surface water features within or adjacent to terrestrial exposure areas will be considered the primary drinking water source. It will be assumed that semi-aquatic wildlife receptors obtain drinking water from the aquatic or transitional exposure areas from which dietary and incidental ingestion exposure pathways are evaluated. Surface water EPCs will be estimated based on COPEC concentrations measured in unfiltered surface water samples. Consistent with other exposure media, preliminary surface water EPCs will be estimated based on maximum COPEC concentrations and refined EPCs will be estimated on a conservative estimate of the central tendency of exposure (e.g., UCL_{mean} EPC concentration).

Probabilistic Exposure Point Concentrations

For probabilistic estimates, wildlife exposures will be evaluated based on the distribution of possible exposure concentrations, in contrast to the point estimate EPCs described above for deterministic models. Distributions of potential exposure concentrations will be developed in the statistical computing and graphics language R (R Core Team, 2013) based on the soil, sediment, and surface water datasets collected during Phase I and Phase II Site Characterization sampling, as described above for the estimation of deterministic EPCs. EPC distributions will represent the range of potential exposure concentrations that may be experienced by a given receptor foraging within exposure areas at the site. The simulated exposure distributions may be truncated at 0, if necessary, to prevent the simulation from selecting negative exposure concentrations. Extreme concentrations at the upper tail of the simulated distribution will be retained in the primary exposure calculations. However, if extreme concentrations are observed at the upper tail of the simulated distribution, the upper tail of the simulated exposure

distribution may be truncated based on the upper tolerance limit of the site-specific dataset and evaluated as a separate scenario in the uncertainty section of the BERA.

Terrestrial Bioaccumulation Relationships

Bioaccumulation of COPECs from soil into terrestrial dietary items, including vegetation, soil invertebrate tissue, and small mammal tissue will be estimated using soil EPCs described in the preceding section and terrestrial bioaccumulation factors (BAFs). BAFs are regression models or constant uptake factors that reflect the relationship between COPEC concentrations in dietary items and concentrations in soil. Differences in concentration are due to COPEC-specific properties that affect its tendency to bioaccumulate in tissue, balanced by the innate ability of the species to regulate body burden levels of the chemical via metabolic and excretory processes. Environmental conditions such as soil moisture, soil pH, and cation exchange capacities significantly influence whether soil COPECs remain bound in the soil matrix or can be mobilized (in a bioavailable form) and released for uptake.

The selection of appropriate BAFs is a critical component to dietary exposure modeling. General approaches for BAF selection have been discussed in Sample and Suter (1994) and USEPA (2007a). An approach that is consistent with these sources was followed in the selection of BAFs for the CFAC Site. The general hierarchy for selection of BAFs based on types of sources is as follows:

1. Use of regression equations derived from paired field- or laboratory-based measurements of COPEC concentrations in dietary items and soil
2. Ratio-derived BAFs developed based on paired data where the BAF is equal to the dietary tissue concentration divided by the soil concentration
3. Modeled equilibrium partitioning-derived BAFs based on physical or chemical characteristics
4. Assumptions based on values common to chemical class

The use of empirically derived BAF ratios is generally preferred over equilibrium partitioning-based BAFs, which are typically calculated based on factors such as log K_{ow} values, fraction of organic carbon in soil, and/or percent of lipids in invertebrates. Also, in selecting ratio-based BAFs, median values are generally preferred for use over maximum or other high-end BAFs (USEPA, 2007a).

Regression equations used to calculate COPEC concentrations in dietary items based on soil concentrations typically take the following form:

$$\ln C_j = B1 \times \ln C_{sub} + B0 \quad (8)$$

where:
$\ln C_j$ = Natural log of the COPEC concentration in dietary item *j*
$\ln C_{sub}$ = Natural log COPEC concentration in substrate (e.g., soil)
B1 = Slope of the food/prey-soil regression
B0 = Intercept of the food/prey-soil regression

Ratio-derived BAFs can be generally presented as follows:

$$C_j = BAF \times C_{sub} \quad (9)$$

where:
C_j = COPEC concentration in dietary item *j* (mg COPEC/kg tissue, dry weight)
C_{sub} = COPEC concentration in soil or sediment (mg COPEC/kg sediment or soil, dry weight)
BAF= Bioaccumulation factor developed based on paired empirical data where the BAF is equal to the dietary tissue concentration divided by the soil concentration (kg substrate/kg tissue, dry weight)

BAFs calculated based on equilibrium partitioning for non-ionic organic compounds are based on the log K_{ow} of the constituent:

$$\log BAF = B1 \times \log K_{ow} + B0 \qquad (10)$$

where:
BAF = Bioaccumulation factor
K_{ow} = Octanol-water partitioning coefficient
B1 = Slope of the BAF-log K_{ow} regression
B0 = Intercept of the BAF-log K_{ow} regression

BAFs calculated based on equilibrium partitioning are applied as ratio-based BAFs to estimate a dietary tissue concentration value. K_{ow} values to estimate BAFs based on equilibrium partitioning were obtained from USEPA Estimation Program Interface Suite K_{ow}Win v. 1.68 software program.

Finally, where ratio-based BAFs are not available and where no equilibrium partitioning method has been developed for calculating BAFs, other methods, such as using BAFs for chemicals within the same class and with similar structural properties, may be adopted as surrogate BAFs.

Terrestrial BAFs will be derived to estimate dry weight concentrations of dietary items, consistent with the reporting of soil COPEC concentrations in dry weight and the calculation of dry weight food ingestion rates FIR_{dw} (see Equation 1). **Table 3** presents a summary of the terrestrial BAFs that will be used to estimate COPEC uptake from soil into terrestrial dietary items, including plants, soil invertebrates, and small mammals. Estimated concentrations in terrestrial items are also presented based on example EPCs. The following sections discuss the basis for selecting terrestrial BAFs to represent uptake into each terrestrial dietary item.

Terrestrial Plants

The following sections provide the basis for estimating COPEC bioaccumulation from soil into terrestrial vegetation for major constituent groups. **Table 3** presents a summary of terrestrial plant BAFs and associated references.

Metals

Soil-to-plant bioaccumulation relationships for metals were primarily selected from literature sources adopted by USEPA in the derivation of Eco-SSLs (**Table 3**). Bioaccumulation relationships derived in Bechtel-Jacobs (1998a) were the primary soil-to-plant uptake relationships adopted in the Eco-SSL development (USEPA, 2007a). Regression equations were used to estimate plant tissue concentrations

for six metals based on relationships derived in Bechtel-Jacobs (1998a) and two metals based on relationships derived in USEPA (2007a). Slope and intercept values used in soil-to-plant regressions are provided in **Table 3**. Bioaccumulation factors were selected for other metals based on median BAFs derived in Bechtel-Jacobs (1998a) or soil-to-plant BAFs derived in Baes et al. (1984).

Other Inorganics

Soil-to-plant bioaccumulation data were limited for fluoride and cyanide (**Table 3**). A ratio-derived soil-to-plant BAF was identified for fluoride based on Baes et al. (1984). Based on Lanno and Menzie (2005), cyanide bioaccumulation into plant tissues was assumed to be negligible for soil uptake pathways. Bioaccumulation and trophic transfer via the food web is not considered to be a significant pathway for inorganic cyanide compounds (Lanno and Menzie, 2005).

Semi-Volatile Organic Compounds – Polycyclic Aromatic Hydrocarbons

Soil-to-plant bioaccumulation relationships for polycyclic aromatic hydrocarbons (PAHs) were selected based on relationships derived for low molecular weight (LMW) and high molecular weight (HMW) PAHs by USEPA in the derivation of Eco-SSLs (USEPA, 2007a). LMW PAHs typically have three or less condensed aromatic rings, while HMW PAHs have four or more aromatic rings. Acceptable compound-specific regression relationships were derived for LMW PAHs, except fluoranthene and naphthalene, and HMW PAHs, except benzo(b)fluoranthene, benzo(e)pyrene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, and pyrene (**Table 3**). Slope and intercept values used in soil-to-plant regressions are provided in **Table 3**. For LMW and HMW PAHs without acceptable regression relationships, median ratio-derived BAFs were used to estimate soil-to-plant uptake (**Table 3**; USEPA, 2007a).

Volatile and Non-PAH Semi-Volatile Organic Compounds

Compound-specific soil-to-plant BAFs were not identified for methylcyclohexane, a volatile organic compound (VOC), or non-PAH semi-volatile organic compounds (SVOCs) identified as soil COPECs, except for pentachlorophenol (PCP). USEPA (2007a) recommends a median BAF from bioaccumulation data for PCP in plants of 5.93. For all other non-ionic compounds in this chemical class, the significant regression equation derived for rinsed plant foliage in USEPA (2007a) will be used to estimate the soil-to-plant BAF as a function of log K_{ow} based on the following relationship:

$$\log BAF = -0.4057 \times \log K_{ow} + 1.781 \qquad (11)$$

where:

BAF = Soil-plant BAF for non-ionic organic constituents
K_{ow} = Octanol-water partitioning coefficient

Compound-specific soil-to-plant BAF values derived from this relationship will be multiplied by the soil EPC to estimate the concentration of non-PAH SVOCs in terrestrial plant tissue (**Table 3**).

Dioxins/Furans

Chemical-specific soil to plant BAFs were not identified for dioxins/furans. Therefore, the regression equation for the uptake of non-ionic organic constituents from soil to rinsed foliage derived in USEPA

(2007a) will be used to estimate uptake from soil to plant tissue for the dioxin/furan congeners identified as COPECs at the site (see Equation 11 above). The application of this regression relationship to estimate soil-to-plant BAFs for dioxin/furans is consistent with the approach used in the Los Alamos National Laboratory (LANL) EcoRisk Database, Release 4.1 (LANL, 2017).

Soil Invertebrates

The following sections provide the basis for estimating COPEC bioaccumulation from soil into soil invertebrate tissue for major constituent groups. **Table 3** presents a summary of soil invertebrate BAFs and associated references.

Metals

Soil-to-soil invertebrate bioaccumulation relationships for metals were primarily selected from literature sources adopted by USEPA in the derivation of Eco-SSLs (**Table 3**). Bioaccumulation relationships derived in Sample et al. (1998a) and Sample et al. (1999) were the primary soil-to-soil invertebrate uptake relationships adopted in the Eco-SSL development (USEPA, 2007a). Regression equations were used to estimate soil invertebrate tissue concentrations for six metals based on relationships derived in Sample et al. (1998a) and Sample et al. (1999). Slope and intercept values used in soil-to-soil invertebrate regressions are provided in **Table 3**. Ratio-derived bioaccumulation factors were selected for other metals based on median BAFs derived in Sample et al. (1998a). The median soil-to-insect BAF reported in USACHPPM (2004) was selected as the BAF for thallium (**Table 3**). Soil-to-soil invertebrate bioaccumulation data were not identified for antimony; therefore, a conservative default BAF of 1 was applied, consistent with USEPA (2007a).

Other Inorganics

Soil-to-soil invertebrate bioaccumulation data were limited for fluoride and cyanide (**Table 3**). A ratio-derived soil-to-plant BAF was identified for fluoride based on the median soil-to-insect BAF reported in USACHPPM (2004). Cyanide bioaccumulation into soil invertebrates was assumed to be negligible for soil uptake pathways, consistent with Lanno and Menzie (2005).

Semi-Volatile Organic Compounds – Polycyclic Aromatic Hydrocarbons

Soil-to-soil invertebrate BAFs for LMW and HMW PAHs were selected from BAFs derived using the partitioning model presented in USEPA (2007a). The model estimates the biota-to-soil water partitioning coefficient (K_{ww}) and divides it by the soil-to-water partitioning coefficient (K_d) to calculate the soil-to-earthworm BAF. USEPA (2007a) used soil organic carbon-to-water partitioning coefficient (K_{oc}) to calculate K_d using the class-specific models presented in Gerstl (1990). Further detail regarding the calculation of soil-to-earthworm BAFs for LMW and HMW PAHs is provided in Section 3.2.2 and Table 5 in USEPA (2007a). Ratio-based soil-to-earthworm BAF values derived in USEPA (2007a) using this modeling approach will be multiplied by soil EPCs to estimate the concentrations of LMW and HMW PAHs in soil invertebrate tissues (**Table 3**).

Volatile and Non-PAH Semi-Volatile Organic Compounds

Compound-specific soil-to-soil invertebrate BAFs were not identified for methylcyclohexane or non-PAH SVOCs identified as soil COPECs, except for PCP. USEPA (2007a) developed a significant regression model to estimate PCP uptake into earthworms; however, the Eco-SSL calculated using this significant regression equation resulted in a soil concentration that was lower than the range of data used to derive the bioaccumulation regression relationship. Therefore, USEPA (2007a) applied a ratio-derived soil-to-earthworm BAF of 14.63 based on the median BAF from empirical studies to estimate soil-to-soil earthworm uptake of PCP. Consistent with USEPA (2007a), the median ratio-derived BAF will be used to estimate PCP concentrations in soil invertebrate tissue in the BERA (**Table 3**).

For other non-ionic compounds in this chemical class, the partitioning model approach applied by USEPA (2007) to estimate soil-to-soil invertebrate BAFs will be used to estimate soil-to-soil invertebrate BAFs in the BERA. Further detail regarding the approach for calculating soil-to-earthworm BAFs for non-ionic organic constituents is provided in Section 3.2.2 in USEPA (2007a). **Table 4** presents the calculations of soil-to-soil invertebrate BAFs for non-PAH SVOC COPECs in soil using the partitioning modeling approach.

Dioxins/Furans

Bioaccumulation of dioxin/furans from soil to earthworm tissues was estimated based on the relationship derived by Sample et al. (1998a):

$$\ln C_{invert} = 3.533 \times \ln C_{soil} + 1.182 \qquad (12)$$

where:

C_{invert} = Concentration in soil invertebrate (mg COPEC/kg tissue, dry weight)
C_{soil} = COPEC concentration in soil (mg COPEC/kg soil, dry weight)

Small Mammals

The following sections provide the basis for estimating COPEC bioaccumulation from soil into mammal tissue for major constituent groups. **Table 3** presents a summary of small mammal BAFs and associated references.

Metals

Soil-to-small mammal bioaccumulation relationships for metals were primarily selected from literature sources adopted by USEPA in the derivation of Eco-SSLs (**Table 3**). Bioaccumulation relationships derived in Sample et al. (1998b) and Baes et al. (1984) were the primary soil-to-small mammal uptake relationships adopted in the Eco-SSL development (USEPA, 2007a). As indicated in **Table 3**, significant regression equations were used to estimate soil invertebrate tissue concentrations for nine metals based on regressions derived in Sample et al. (1998b). Slope and intercept values used in soil-to-small mammal regressions are provided in **Table 3**. A median ratio-derived soil-to-small mammal BAF was selected for mercury, consistent with LANL (2017).

Ratio-derived bioaccumulation factors were selected for antimony, barium, beryllium, and thallium based on diet-to-beef transfer factors reported in Baes et al. (1984). Consistent with USEPA (2007a), in the absence of alternative bioaccumulation relationships for metals, soil-to-beef transfer factors reported for metals in Baes et al. (1984) were used to estimate soil-to-small mammal BAFs based on the following:

$$BAF_{soil-mammal} = BAF_{soil-diet} \times 50 \times Tf_{diet-mammal} \quad (13)$$

where:

$BAF_{soil-mammal}$ = Soil-to-small mammal BAF (kg soil/kg mammal tissue, dry weight)
$BAF_{soil-diet}$ = Soil-to-diet BAF; conservatively assumed to be a soil invertebrate diet (kg soil/kg tissue, dry weight)
$Tf_{diet-mammal}$ = Transfer factor from diet-to-mammal tissue (day/kg mammal tissue)
50 = Cattle food intake rate of 50 kg/day assumed by Baes et al. (1984)

Diet-to-beef transfer factors from Baes et al. (1984) for antimony, barium, beryllium, and thallium are provided in **Table 3**. Soil-to-small mammal BAF values derived using this approach will be multiplied by the soil EPC to estimate the concentration of these select metals in small mammal tissue (**Table 3**).

Other Inorganics

Soil-to-small mammal bioaccumulation data were limited for fluoride and cyanide (**Table 3**). Ratio-derived soil-to-small mammal BAFs were derived by LANL (2015) for fluoride; the LANL-derived soil-to-small mammal BAF values will be multiplied by soil EPCs to estimate the concentrations of fluoride in small mammal tissue (**Table 3**). Cyanide bioaccumulation into small mammals was assumed to be negligible for soil uptake pathways, consistent with Lanno and Menzie (2005).

Semi-Volatile Organic Compounds – Polycyclic Aromatic Hydrocarbons

Small mammal bioaccumulation data for LMW and HMW PAHs are limited. However, USEPA (2007a) assumes that PAH bioaccumulation is minimal due to the rapid metabolism of these compounds following ingestion by birds and mammals. Consistent with USEPA (2007a), the bioaccumulation of LMW and HMW PAHs in small mammal tissue is assumed to be negligible (**Table 3**).

Volatile and Non-PAH Semi-Volatile Organic Compounds

Compound-specific soil-to-small mammal bioaccumulation data were limited in general literature sources for methylcyclohexane and most non-PAH SVOC soil COPECs. USEPA (2007a) developed a general regression equation for the accumulation of PCP from the diet to chicken tissue; this relationship was assumed to be representative of potential accumulation from the diet to small mammal tissues (USEPA, 2007a). LANL (2015) calculated soil-to-small mammal BAFs for phthalates and hexachlorobenzene. These soil-to-small mammal tissue BAFs were also selected to represent potential bioaccumulation into small mammals at the Site (**Table 3**).

For methylcyclohexane and other non-PAH SVOCs, data for uptake from soil into small mammal tissue are lacking. For these constituents, the model used in the LANL (2017) EcoRisk food chain model to estimate the transfer factor for the flesh of prey items (TF_flesh_dw) will be used to estimate the BAF_{soil-}

$_{mammal}$ value in the BERA. The LANL (2017) model multiplies the uptake factor for beef/cattle, derived using the method recommended in EPA (2005j), by maximum ingestion rates and dietary BAFs of prey items consisting of other modeled receptors with lower trophic orders. To retain consistency with the LANL EcoRisk model, the same receptor species that were assumed in that model to be prey items for higher trophic order receptors were used to develop the CFAC BAFs (i.e., American robin, deer mouse, desert cottontail, and short-tailed shrew). The model equation is as follows:

$$BAF_{soil-mammal} = BAF_{beef} \times \left[\frac{\left(FIR_{MAX} \times BAF_{MAX\ Plant/Invert} + SIR_{MAX}\right)}{(1-MC)}\right] \quad (14)$$

where:

$BAF_{soil-mammal}$ = Soil-to-small mammal BAF (kg soil/kg flesh, dry weight)
BAF_{beef} = Diet-beef biotransfer factor (day/kg beef, wet weight)
FIR_{max} = Maximum ingestion rate for prey species (kg food/day, dry weight)
$BAF_{MAX\ Plant/Invert}$ = Maximum BAF for plant or invertebrate dietary items of the prey species (kg soil, dry weight/kg tissue, wet weight)
$IR_{soilMAX}$ = Maximum ingestion rate of soil for prey species (kg soil/day, dry weight)
MC = Moisture content of flesh (assumed 68 percent)

The biotransfer to beef factor is estimated using the following model described in Research Triangle Institute (RTI) (2005) and recommended by EPA (2005j):

$$\log BAF_{beef} = Fat_{beef} \times (-0.099 \times \log {K_{ow}}^2 + 1.07 \times \log K_{ow} - 3.56) \quad (15)$$

where:

BAF_{beef} = Diet-beef biotransfer factor (day/kg beef, wet weight)
Fat_{beef} = Fat content of beef; assumed to be 19 percent or 0.19 based on LANL (2017)
Kow = Octanol-water partition coefficient

Table 5 presents calculated soil-to-small mammal BAFs estimated for methylcyclohexane and non-PAH SVOCs lacking soil-to-mammal BAFs from other literature sources.

Dioxins/Furans

Sample et al. (1998b) developed bioaccumulation relationships for estimating uptake of TCDD and tetrachlorinated dibenzofuran (TCDF) into small mammal tissue based on empirical data for multiple organism groups. A simple regression equation was recommended to estimate TCDD concentrations in small mammal tissue based on soil concentrations. A median ratio-derived soil-to-small mammal BAF was recommended to estimate TCDF concentrations in small mammal tissue. Consistent with the recommendations in Sample et al. (1998b), the simple regression equation will be used to estimate concentrations of TCDD and other dioxin congeners in small mammals; the median soil-to-small mammal BAF for TCDF will be used to estimate concentrations of TCDF and other furan congeners (**Table 3**).

Aquatic Bioaccumulation Relationships

The development of bioaccumulation relationships in aquatic environments will use similar approaches to those described in the preceding section for terrestrial environments. Bioaccumulation of COPECs

from sediment or surface water into aquatic dietary items of semi-aquatic wildlife receptors, including benthic invertebrates and fish, will be estimated using the sediment EPCs and biota-sediment accumulation factors (BSAFs) or surface water EPCs and bioconcentration factors (BCFs). BSAFs or BCFs will be developed based on regression models or constant uptake factors that reflect the relationship between COPEC concentrations in dietary items and concentrations in sediment or surface water. Like BAFs for soil, the uptake of COPECs into biota within the aquatic environment is influenced by COPEC-specific properties, sediment characteristics (e.g., organic carbon content), receptor physiology, and the characteristics of dietary items (e.g., lipid content).

Table 5 presents a summary of the aquatic BSAFs or BCFs that will be used to estimate COPEC bioaccumulation from sediment or surface water into benthic invertebrates and fish. Estimated COPEC concentrations in aquatic biota are expressed on a dry weight basis based on BSAFs or BCFs derived on a dry weight basis. The following sections discuss the basis for selecting aquatic BSAFs or BCFs to represent uptake into each potential dietary item of semi-aquatic wildlife receptors of concern.

Benthic Invertebrates

Literature-based BSAFs or BCFs will be used to estimate the bioaccumulation of COPECs into benthic invertebrates as a function of sediment or surface water concentrations, respectively (**Table 5**). The following sections provide the basis for estimating COPEC bioaccumulation into benthic invertebrates for major constituent groups.

Metals

Metal concentrations in benthic invertebrates were estimated based on BSAFs presented in literature compilations (e.g., Sample et al., 1998b) and individual studies (**Table 5**). Median BSAF values provided in Sample et al. (1998b) were preferentially used to estimate benthic invertebrate concentrations for metals included in the compilation. For metals not included in Sample et al. (1998b), BSAF values were estimated from individual literature studies. The BSAF for aluminum was estimated as the ratio of mean oligochaete (*Lumbriculus variegatus*) tissue concentrations (dry weight) to mean whole sediment aluminum concentrations (dry weight) reported by Stanley et al. (2010). The median BSAF calculated from the ratios of mean benthic invertebrate tissue and mean whole sediment concentrations reported by Dovick et al. (2015) was used to estimate antimony bioaccumulation into benthic macroinvertebrates. Median BSAFs calculated from paired benthic invertebrate and sediment data reported by Hamilton et al. (2002) were used to estimate concentrations of barium, beryllium, selenium, and vanadium (**Table 5**). Sediment bioaccumulation data for thallium were limited; however, biomonitoring data from Turner et al. (2013) were used to estimate a BSAF for deposit-feeding invertebrates. In the absence of other data, a BSAF calculated as the mean concentration in deposit-feeding invertebrates and mean sediment concentration reported for the Plym estuary by Turner et al. (2013) was used as a BSAF for thallium (**Table 5**).

Other Inorganics

Bioaccumulation information for cyanide and fluoride was evaluated from literature reviews and primary literature. Based on Lanno and Menzie (2005), cyanide bioaccumulation into benthic invertebrates was assumed to be negligible for sediment and surface water uptake pathways.

Bioaccumulation and trophic transfer via the food web is not considered to be a significant pathway for inorganic cyanide compounds (Lanno and Menzie, 2005).

Aqueous exposure to the fluoride ion (F^-) is the predominant bioaccumulation pathway for aquatic organisms. Given that aqueous exposure is the predominant bioaccumulation pathway, data reported by Aguirre-Sierra et al. (2013) were used to relate aqueous F^- concentrations to F^- concentrations in muscle tissue and exoskeleton of the freshwater white-clawed crayfish (*Austropotamobius pallipes*). As illustrated in Figure 1a, fluoride bioaccumulation in crayfish exoskeleton and muscle tissue increased exponentially from the control treatment (0.18 ± 0.07 mg/L) to the highest test treatment (84.8 ± 12.4 mg/L). Greater fluoride bioaccumulation was observed in the crayfish exoskeleton relative to muscle tissue, consistent with other studies that indicate greater accumulation in invertebrate exoskeletons (Sands et al. 1998; Camargo, 2003).

Based on the water-to-invertebrate relationships derived from Aguirre-Sierra et al. (2013), F^- concentrations in benthic invertebrate tissues will be estimated in the BERA as a function of F^- concentrations in unfiltered surface water using the relationship for crayfish muscle tissue (Figure 1a; **Table 5**):

$$C_{invertebrates} = 24.253 \times e^{(0.0773 \times C_{water})} \qquad (16)$$

where:

$C_{invertebrates}$ = Concentration in invertebrate tissue (mg F^-/kg dry weight)
C_{water} = Concentration in unfiltered surface water (mg F^-/L)

The crayfish muscle bioaccumulation relationship derived from data reported by Aguirre-Sierra et al. (2013) was selected to represent the more edible and digestible portions of crayfish tissue that may be consumed by wildlife. Further evaluation of this assumption may be warranted in the BERA pending an analysis of the potential influence of this uncertainty on the risk characterization of F- exposure to semi-aquatic wildlife.

Semi-Volatile Organic Compounds – Polycyclic Aromatic Hydrocarbons

PAH concentrations in benthic invertebrates were estimated based on the biota-sediment accumulation relationship described by DiToro and McGrath (2000) in the development of the target lipid model. BSAFs for PAH compounds were estimated on an organic carbon and lipid-normalized basis as a function of K_{ow}:

$$BSAF_{OC} = \frac{C_{lipid}}{C_{oc}} = K_{ow}{}^{-0.038} \qquad (17)$$

where:

$BSAF_{oc}$ = BSAF normalized by organism lipid content and sediment organic carbon content (kg organic carbon/kg lipid)
C_{lipid} = Tissue lipid concentration (mg PAH/kg lipid)
C_{oc} = Sediment organic carbon concentration (mg PAH/kg organic carbon)
K_{ow} = Octanol-water partitioning coefficient

Organic carbon and lipid-normalized BSAFs were estimated on a dry weight basis using assumed lipid and organic carbon content in sediments as follows:

$$BSAF_{dw} = BSAF_{oc} \times f_{lipid} \times \frac{1}{f_{oc}} \qquad (18)$$

where:

$BSAF_{dw}$ = BSAF specific to prey type and COPEC (kg sediment/kg tissue, dry weight)
$BSAF_{oc}$ = Organic carbon and lipid-normalized BSAF specific to prey type and COPEC (kg organic carbon/kg lipid)
f_{lipid} = Fraction of lipid in dietary items (0.065 assumed in **Table 5** for benthic invertebrates)
f_{oc} = Fraction of organic carbon in sediment (0.01 assumed in **Table 5**)

PAH-specific $BASF_{dw}$ values will be multiplied by the COPEC concentration in sediment (mg/kg dry weight) to estimate the COPEC concentration in the dietary item (mg/kg dry weight).

Semi-Volatile Organic Compounds – Non-Polycyclic Aromatic Hydrocarbon

Bioaccumulation of other non-ionic organic compounds was assumed to be similar to PAH bioaccumulation. Therefore, BSAFs for non-PAH SVOCs were estimated as a function of K_{ow} using the identical procedures described in the preceding section for PAHs (**Table 5**).

Fish

Literature-based BASFs or BCFs will be used to estimate the bioaccumulation of COPECs into fish tissue as a function of sediment or surface water concentrations, respectively (**Table 5**). The following sections provide the basis for estimating COPEC bioaccumulation into fish for major constituent groups.

Metals

Metal bioaccumulation into fish tissue was estimated based on the bioconcentration of metals from surface water into tissue. Sample et al. (1996b) was selected as a preferential source of BCFs based on a compilation of metal BCF values identified in the literature (**Table 5**). BCF values were not available in Sample et al. (1996b) for barium, silver, and vanadium; therefore, literature studies were reviewed to identify potential bioaccumulation relationships between surface water and fish tissue concentrations. A BCF of 74.4 for barium bioaccumulation into male fish carcass reported by Nakamoto and Hassler (1992) will be used to estimate barium concentrations in fish tissue. A BCF of 106 reported in study of silver bioaccumulation into Common Carp (*Cyprinus carpo*) will be used to estimate silver bioaccumulation into fish tissue (Laplace et al, 1992). CECBP (2008) compiled a range of BCF values from 365-630 for vanadium uptake into fish. Due to the paucity of data to support the calculation of a BCF for vanadium, the most conservative BCF value of 630 will be used to estimate fish tissue concentrations.

BCFs reported by Sample et al. (1996b) are based on wet weight fish tissue concentrations; therefore, BCF values were divided by 0.25 based on assumed percent solids of 25 percent to estimate fish tissue concentrations on a dry weight basis (**Table 5**). The BCF values for barium, silver, and vanadium were also divided by 0.25, based on BCFs being reported on a wet weight tissue basis.

Other Inorganics

Cyanide and fluoride bioaccumulation into fish tissue were evaluated based on literature reviews and primary literature studies. Consistent with Lanno and Menzie (2005), cyanide bioaccumulation into fish tissue was assumed to be negligible for sediment and surface water uptake pathways.

As previously stated for benthic invertebrates, aqueous exposure is the predominant F^- bioaccumulation pathway for aquatic organisms. Like invertebrates, F^- bioaccumulation in fish tends to be greatest in skeletal tissues, including bones, cartilage, and gills. Shi et al. (2009) evaluated the bioaccumulation of F^- from aqueous exposure into multiple tissue compartments in Siberian sturgeon (*Acipenser baerii*). As illustrated in Figure 1b, F^- concentrations increased in skeletal tissues (bone, cartilage, and gills) with increasing water concentrations ranging from the control treatment (0.26 ± 0.07 mg/L) to the highest test treatment (51.8 ± 3.5 mg/L). However, F^- concentrations in soft tissues, including skin, muscle, and viscera, generally remained unchanged with increasing aqueous exposure.

Based on the assumption that F^- concentrations in soft fish tissue, the more edible and digestible portions of fish for potential piscivorous consumers, will not exceed the concentrations in gill tissue, the bioaccumulation relationship derived using data from Shi et al. (2009) for gill tissue will be used as a conservative estimate of F^- concentrations in soft tissue compartments of fish (Figure 1b). F^- concentrations in fish tissue will be estimated in the BERA as a function of F^- concentrations in unfiltered surface water using the relationship derived for bioaccumulation into fish gills (**Table 5**):

$$C_{fish} = 42.377 \times \ln C_{water} + 214.34 \qquad (19)$$

where:

C_{fish} = Concentration in fish tissue (mg F^-/kg dry weight)
C_{water} = Concentration in unfiltered surface water (mg F^-/L)

The use of the fish gill bioaccumulation relationship derived from data presented in Shi et al. (2009) conservatively estimates F- concentrations in soft tissues that may be preferentially consumed by piscivorous wildlife receptors (e.g., mink) that typically forage on soft tissue (e.g., skin, muscle, and viscera) and forgo fish carcasses that contain mostly skeletal tissue. The use of this relationship also assumes that whole-body fish tissue concentrations will not exceed concentrations observed in fish gill tissue for those piscivorous wildlife that may consume the entire fish. Further evaluation of these assumptions may be warranted in the BERA pending the potential influence of this uncertainty on the risk characterization of F- exposure to semi-aquatic wildlife.

Semi-Volatile Organic Compounds – Polycyclic Aromatic Hydrocarbons

PAH concentrations in fish tissue were estimated based on the K_{ow}-based biota-sediment accumulation relationship used to estimate PAH concentrations in benthic invertebrates (DiToro and McGrath, 2000). Estimated concentrations were based on the equations presented in the preceding section for benthic invertebrates and an assumed dry weight lipid fraction in fish of 0.085 (**Table 5**). The application of the BSAF relationship from DiToro, and McGrath (2000) conservatively assumes that exposure and uptake to fish within the water column does not exceed exposure and uptake in sediment and pore water within the benthic environment.

Semi-Volatile Organic Compounds – Non-Polycyclic Aromatic Hydrocarbons

Fish tissue concentrations of non-PAH SVOCs were estimated using the K_{ow}-based biota-sediment accumulation relationship used to estimate PAH concentrations in fish tissue, as described in the preceding section (DiToro and McGrath, 2000). Consistent with the approach for benthic invertebrates, this approach assumes that the bioaccumulation of other non-ionic organic compounds is a function of compound-specific K_{ow}, similar to PAHs.

Area Use Factors

In dietary exposure models, the AUF reflects the proportion of the dose that a receptor may obtain while foraging within the a given exposure area. The AUF is primarily estimated based on the ratio of the size of the exposure area to the area of the receptor foraging range. Species with very relatively small home ranges (e.g., meadow vole or short-tailed shrew) may forage entirely within the study area. However, for species with larger home ranges (e.g., large birds and mammals), most of the receptor diet may come from outside of an exposure area or the Site. If the foraging range of a receptor is greater than an exposure area, the EDD will be calculated as the sum of AUF-weighted doses obtained from the exposure areas within the typical home range of the receptor.

Available literature sources use various metrics to represent the size of the area used by a receptor: feeding or foraging radius, feeding or foraging distance, and home range or territory size, etc. In most cases, the size of the area used by a receptor for foraging and feeding is reported in acres and is referred to as the home range or territory. For initial exposure modeling, AUFs will be assigned a value of 1 (i.e., 100 percent foraging within the exposure area) and adjusted subsequently in the refined evaluation based on the corresponding sizes of the receptor-specific home range and the exposure area. Refined AUFs may also account for developed or unvegetated areas of the Site that do not provide habitat or forage base for wildlife receptors; these areas may be excluded from refined dietary exposure estimates due to the absence of forage base.

Seasonal use may also be considered in the calculation of the AUF to estimate the exposure duration for receptors that may only be present seasonally at the Site. Seasonal use will initially be assumed to be 100 percent; however, estimates of seasonal use may be incorporated into the AUF for the refined exposure evaluation in the BERA to address the potential uncertainty associated with the duration of exposure for seasonal receptors at the Site.

Toxicity Reference Values

TRVs will be derived to evaluate the potential for adverse ecological effects associated with the dietary doses estimated using the approaches described in the preceding sections. Two tiers of chronic TRVs representing no-observed-adverse-effect levels (NOAELs) and LOAELs for growth and reproduction endpoints will be identified to evaluate the potential for adverse effects via wildlife ingestion pathways:

- Low TRV (TRV_{Low}): Represents the geometric mean NOAEL TRV identified in literature studies.
- High TRV (TRV_{High}): Represents a TRV-based on chronic exposure, that estimates a representative LOAEL in literature studies.

The two tiers of TRVs will be used to evaluate potential wildlife exposure based on EDDs calculated using preliminary and refined exposure assumptions and EPCs. For receptors with special regulatory status (i.e., threatened or endangered species), the TRV_{Low} will be used to estimate the potential for adverse effects to potential individual receptors within the population.

Preliminary TRVs for bioaccumulative COPECs were identified from primarily peer-reviewed compilations of toxicity data for ecological risk assessment including:

- USEPA Eco-SSLs (USEPA, 2005a)
- LANL EcoRisk (LANL, 2017)
- ORNL *Toxicological Benchmarks for Wildlife: 1996 Revision* (Sample et al., 1996b)

At the request of USEPA, LOAELs provided in TechLaw (2008) and the approach used to derive TRVs in TechLaw (2008) were also considered in the selection of TRVs. TRVs presented in *Development of Toxicity Reference Values for Conducting Ecological Risk Assessment at Naval Facilities in California, Interim Final* (Engineering Field Activity West, 1998) were also considered as a source for toxicity reference values. For constituents lacking toxicity data from these compilations, literature sources were reviewed to identify appropriate TRVs. The following sections summarize the basis for selecting preliminary TRVs from literature/database sources for the BERA; a summary of the TRVs and associated sources is provided in **Table 7**. The BERA Report will also include an appendix that documents the basis for deriving final TRVs used in dietary exposure modeling.

Metals

Avian and mammalian TRVs for metals were selected primarily from TRVs used by the USEPA to develop Eco-SSLs or derived from studies accepted by the USEPA for Eco-SSL derivation (USEPA, 2005). The Eco-SSL approach generally adopted TRVs based on the geometric mean of NOAEL doses for growth and reproduction endpoints from accepted studies. However, in cases where the geometric mean of growth and reproduction NOAELs exceeded the lowest bounded LOAEL, the Eco-SSL conservatively selected the highest bounded NOAEL below the lowest bounded LOAEL for growth, reproduction, or survival as the preferred TRV. Other endpoints were considered for metals lacking data on growth, reproduction, or survival data.

Avian TRVs were identified for metal COPECs identified in the SLERA, except antimony and beryllium (**Table 7**). Most avian NOAEL TRVs for metals were obtained from the TRVs used by the USEPA to develop Eco-SSLs (**Table 7**); however, avian Eco-SSL TRVs were not available for mercury and thallium. Avian TRVs identified for mercury by Sample et al. (1996b) will be used as representative NOAEL and LOAEL TRVs in the BERA (**Table 7**). For thallium, avian NOAEL and LOAEL endpoints selected in the LANL EcoRisk database for the derivation of ecological screening levels (ESLs) were identified as preliminary TRVs for the BERA. Avian TRVs were not identified in the literature for antimony or beryllium; therefore, potential avian effects related to the estimated dietary exposure of these metals will be addressed as an uncertainty in the BERA.

Mammalian TRVs were selected primarily from TRVs used by the USEPA to develop Eco-SSLs or derived from studies accepted by the USEPA for Eco-SSL derivation (**Table 6**). NOAEL TRVs were selected based on TRVs used in the Eco-SSL derivation for metals, except for aluminum, mercury, and thallium. Consistent with USEPA (2003b), mammalian exposure to aluminum will be evaluated based on soil

conditions, particularly pH, that control the mobility and bioavailability in soils (EHS Support, 2018). The NOAEL TRVs identified for mercury by Sample et al. (1996b) will be used as the representative NOAEL; however, a corresponding mammalian LOAEL was not identified for mercury (**Table 6**). For thallium, NOAEL and LOAEL endpoints were selected from the mammalian study selected in the LANL EcoRisk database (Formigli et al., 1986) for the derivation of ESLs.

Other Inorganics

Avian and mammalian TRVs for cyanide and fluoride were identified based on studies selected for use in calculating ESLs in the LANL EcoRisk Database (LANL, 2017; **Table 6**). For cyanide, an oral dosing study evaluating American kestrel (*Falco sparverius*) survival conducted by Wiemeyer et al. (1986) will be used as the basis for avian TRVs (**Table 6**). A chronic critical life stage study evaluating reproductive effects in rats conducted by Tewe and Maner (1981) will be used as the basis for mammalian TRVs for cyanide. For fluoride, a dietary study of reproductive effects of chronic-critical life stage exposure of Eastern screech owl (*Megascops asio*) conducted by Pattee et al. (1988) will be used as the basis of the avian NOAEL and LOAEL (**Table 6**). A chronic study evaluating potential reproductive effects of dietary fluorine in mink conducted by Aulerich et al. (1997) will be used the basis for the mammalian NOAEL and LOAEL (**Table 6**).

Semi-Volatile Organic Compounds – Polycyclic Aromatic Hydrocarbons

Consistent with USEPA (2007f), dietary exposure to LMW and HMW PAHs will be evaluated as an aggregate dose of each molecular weight group due to the common toxicological properties of PAH compounds within each group.

Avian toxicological studies for LMW and HMW are limited. USEPA (2007f) did not identify a sufficient number of acceptable studies to derive avian Eco-SSLs for either class of PAHs. Of the avian studies accepted by USEPA (2007f), the minimum NOAEL and LOAEL endpoints for growth reported by Trust et al. (1994) were selected as HMW PAH avian TRVs for the BERA (**Table 6**). For avian exposure to LMW PAHs, physiological endpoints from a chronic dietary exposure (7 months) to mallard duck reported by Patton and Dieter (1980) were selected as LMW PAH avian TRVs for the BERA (**Table 6**).

Mammalian NOAELs for LMW and HMW PAHs were selected based on TRVs used by USEPA in the derivation of Eco-SSLs (USEPA, 2007f). The mammalian NOAEL TRV for LMW PAHs was selected as the geometric mean of NOAELs for growth and reproduction endpoints (**Table 6**). The geometric mean of HMW PAH mammalian endpoints for growth and reproduction evaluated in Eco-SSL studies was 18 mg/kg-bw/day; however, the mammalian Eco-SSL for HMW PAH was conservatively derived based on the highest bounded NOAEL below the lowest bounded LOAEL for growth, reproduction, or survival (0.615 mg/kg-bw/day). The TRV of 0.615 mg/kg-bw/day used in the derivation of the mammalian Eco-SSL for HMW PAHs was conservatively selected as the HMW mammalian NOAEL for the BERA. However, given that this NOAEL TRV is two orders of magnitude below the geometric mean of mammalian growth and reproduction NOAELs for HMW PAHs in Eco-SSL studies, further evaluation of mammalian exposure to HMW PAHs in the BERA will include consideration of the range of NOAEL endpoints for growth and survival. Mammalian LOAEL TRVs for LMW and HMW PAHs selected for the BERA are consistent with TechLaw (2008) based on the geometric mean of LOAEL endpoints for growth and reproduction (**Table 6**).

Semi-Volatile Organic Compounds – Non-Polycyclic Aromatic Hydrocarbons

Limited toxicological data are available for the development of TRVs for non-PAH SVOCs. Avian TRVs were identified in the LANL EcoRisk database (LANL, 2017), Sample et al. (1996b), and USEPA (2007g) for 4 of the 12 non-PAH SVOC COPECs, including two of the phthalate ester compounds, bis(2-ethylhexyl) phthalate and di-n-butyl phthalate (**Table 6**). Avian TRVs for di-n-butyl phthalate were selected as surrogate values that will be used to evaluate butyl benzylphthalate and di-n-octyl phthalate (**Table 6**). The avian NOAEL TRV for pentachlorophenol was selected consistent with USEPA (2007g); the LOAEL TRV for pentachlorophenol was estimated as the geometric mean of LOAEL endpoints for growth and reproduction, consistent with TechLaw (2008). No avian TRVs were identified for the remaining non-PAH SVOC COPECs (**Table 6**). Potential avian effects related to the estimated dietary exposure of these non-PAH SVOCs will be addressed as an uncertainty in the BERA.

Literature-based TRVs for mammalian receptors were identified for 7 of the 12 non-PAH SVOCs (**Table 6**). The selection of mammalian TRVs for non-PAH SVOCs was consistent with the value selected by LANL EcoRisk for bis(2-ethylhexyl) phthalate, butyl benzylphthalate, di-n-octyl phthalate, and hexachlorobenzene (**Table 6**). The mammalian NOAEL for pentachlorophenol was selected consistent with USEPA (2007g); the pentachlorophenol LOAEL was estimated as the geometric mean of LOAEL endpoints for growth and reproduction, consistent with TechLaw (2008). NOAEL and LOAEL endpoints reported by Kociba et al. (1977) in a chronic dietary study of Sprague-Dawley rats were selected as NOAEL and LOAEL TRVs for hexachlorobutadiene (**Table 6**). Sufficient information was not identified to develop TRVs for the remaining five SVOCs; mammalian dietary exposure to these non-PAH SVOCs will be addressed as an uncertainty in the BERA.

Dioxin/Furans

Dietary exposure to dioxin/furan compounds will be evaluated based on the potential additive toxicity of dioxin/furan compounds based on the toxicity equivalence methodology (USEPA, 2008a). A dietary dose will be calculated for the 17-individual dioxin/furan compounds in each sample. The EDD for each compound will be multiplied by the compound-specific TEF for birds or mammals to express the dose toxicity equivalence concentration (TEC) to the toxicity of TCDD. TECs of the 17 dioxin/furan compounds will be summed to calculate an overall TEC for comparison with dietary TRVs for 2,3,7,8-TCDD derived for birds and mammals.

Avian and mammalian TRVs for 2,3,7,8-TCDD were selected consistent with Sample et al. (1996b) and the LANL EcoRisk database (LANL, 2017), respectively (**Table 6**). Sample et al. (1996b) identified reproductive NOAEL and LOAEL endpoints (egg production and hatchability) for ring-necked pheasant in a study reported by Nosek et al. (1992). Farmahin (2012, 2013) noted that bird species fall into one of three sensitivity categories (high, medium, and low) for dioxins, with pheasants falling into the middle category. At the request of EPA, a downward adjustment of a factor of 8 (reflecting the difference in sensitivity between bird species in the moderate and highly sensitive categories) was applied to the avian TRV for 2,3,7,8-TCDD. However, as stated in Farmahin (2012), using toxicity data associated with the most sensitive bird species to evaluate dioxins would likely overestimate potential risk of adverse effects, and could lead to inappropriate decisions about remedial options at contaminated sites. The LANL EcoRisk database selected mammalian NOAEL and LOAEL values based on chronic reproductive endpoints from a multi-generational study of Sprague-Dawley rats reported by Murray et al. (1979).

NOAEL and LOAEL TRVs from these sources were selected to evaluate dietary TECs for avian and mammalian receptors of concern in the BERA (**Table 6**).

Methylcyclohexane	3.590	●			Yes				Yes
m,p-Xylene	3.090	●			No				
o-Xylene	3.090	●			No				

Notes:
COPEC, constituent of potential ecological concern
●, COPEC identified in the SLERA
●, COPEC identified in the BERA Work Plan as having a detection in at least one sample and had no associated ecological screening value.
USEPA, United States Environmental Protection Agency
PBT, persistent bioaccumulative toxic
Eco-SSL, ecological soil screening level
NA, not applicable
PAH, polycyclic aromatic hydrocarbons
SVOC, semi-volatile organic compounds
HMW, high molecular weight
LMW, low molecular weight

Notes:

a, ac, acres; km, kilometers

b, Estimated food ingestion rate (kg/day dry weight) for insectivorous birds = $(0.54[\text{Body Weight in grams}]^{0.705})/1000$ (Nagy 2001);

c, Estimated food ingestion rate (kg/day dry weight) for omnivorous birds = $(0.670[\text{Body Weight in grams}]^{0.627})/1000$ (Nagy 2001);

d, Estimated food ingestion rate (kg/day dry weight) for carnivorous birds = $(0.849[\text{Body Weight in grams}]^{0.663})/1000$ (Nagy 2001);

e, Estimated food ingestion rate (kg/day dry weight) for Carnivora = $(0.102[\text{Body Weight in grams}]^{0.864})/1000$ (Nagy 2001);

f, Estimated food ingestion rate (kg/day dry weight) for Rodentia = $(0.332[\text{Body Weight in grams}]^{0.774})/1000$ (Nagy 2001);

g, Estimated food ingestion rate (kg/day dry weight) for insectivorous mammals = $(0.373[\text{Body Weight in grams}]^{0.622})/1000$ (Nagy 2001);

h, Based on assumption from Sample and Suter 1994 that substrate ingestion is neglible for piscivores;

i, Estimated drinking water ingestion rate for birds = $(0.059\times[\text{body weight in kg}]BW^{0.67}$ (Caulder and Braun, 1983)

j, Estimated drinking water ingestion rate for mammals = $(0.099\times[\text{body weight in kg}]BW^{0.90}$ (Caulder and Braun, 1983)

k, As cited in the Montana Field Guide, accessed at http://fieldguide.mt.gov/default.aspx

l, Literature-based incidental substrate ingestion rate was not identified; assumed limited incidental ingestion based on habitat preference for fast-moving streams with sandy/rocky bottoms.

m, Based on red fox soil ingestion rate assuming the soil ingestion rate of top predators does not exceed the soil ingestion rate of red fox.

SD, standard deviation

Table 3
Estimated Concentrations in Dietary Items of Terrestrial Receptors
Draft Technical Memorandum: Proposed Wildlife Exposure Modeling Approach
Columbia Falls Aluminum Company
Columbia Falls, Montana

Notes:

Maximum soil exposure point concentrations are example values to illustrate the calculation of COPEC concentrations in tissue; these values are not representative of exposure concentrations at the Site.

a, Plant tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]). Slopes (B1) and intercepts (B0) are as follows:

Analyte	B0	B1	Data Source
Antimony	-3.233	0.938	USEPA (2007)
Beryllium	-0.5361	0.7345	USEPA (2007)
Cadmium	-0.475	0.546	Bechtel-Jacobs (1998)
Copper	0.668	0.394	Bechtel-Jacobs (1998)
Lead	-1.328	0.561	Bechtel-Jacobs (1998)
Mercury	-0.996	0.544	Bechtel-Jacobs (1998)
Nickel	-2.223	0.748	Bechtel-Jacobs (1998)
Selenium	-0.677	1.104	Bechtel-Jacobs (1998)
Zinc	1.575	0.554	Bechtel-Jacobs (1998)
Acenaphthene	-5.562	-0.8556	USEPA (2007)
Acenaphthylene	-1.144	0.791	USEPA (2007)
Anthracene	-0.9887	0.7784	USEPA (2007)
Benzo(a)anthracene	-2.7078	0.5944	USEPA (2007)
Benzo(a)pyrene	-2.0615	0.975	USEPA (2007)
Benzo(g,h,i)perylene	-0.9313	1.1829	USEPA (2007)
Benzo(k)fluoranthene	-2.1579	0.8595	USEPA (2007)
Chrysene	-2.7078	0.5944	USEPA (2007)
Fluorene	-5.562	-0.8556	USEPA (2007)
Phenanthrene	-0.1665	0.6203	USEPA (2007)

b, Soil-to-plant BAF based on K_{ow} model for non-ionic organic compounds (rinsed foliage data) provided in USEPA (2005), where: log BAF = -0.4057(log K_{ow}) + 1.781; log K_{ow} values obtained from EPA EpiSuite V. 1.69, KOWWIN module.

c, Soil-invertebrate bioaccumulation factor could not be identified; therefore, a conservative default accumulation factor of 1.0 was assummed.

d, Soil invertebrate tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]) and slopes (B1) and intercepts (B0) are as follows:

Analyte	B0	B1	Data Source
Arsenic	-1.421	0.706	Sample et al. (1999)
Cadmium	2.114	0.795	Sample et al. (1999)
Lead	-0.218	0.807	Sample et al. (1999)
Manganese	-0.809	0.682	Sample et al. (1999)
Selenium	-0.075	0.733	Sample et al. (1999)
Zinc	4.449	0.328	Sample et al. (1999)
2,3,7,8-TCDD	3.533	1.182	Sample et al. (1998a)

e, Bioaccumulation factor estimated as the product of the soil-plant and ingestion-beef factors reported in Baes et al. (1984)

f, Median soil-to-plant uptake factors reported in Bechtel (1998a) were used as bioaccumulation factors.

g, Small mammal tissue concentrations (mg/kg dry weight) calculated based on regression models, where ln([tissue]) = B0 + B1(ln[soil]) and slopes (B1) and intercepts (B0) are as follows:

Analyte	B0	B1	Data Source
Arsenic	-4.8471	0.8188	Sample et al. (1998b)
Cadmium	-1.2571	0.4723	Sample et al. (1998b)
Chromium	-1.4599	0.7338	Sample et al. (1998b)
Cobalt	-4.4669	1.307	Sample et al. (1998b)
Copper	2.042	0.144	Sample et al. (1998b)
Lead	0.0761	0.4422	Sample et al. (1998b)
Nickel	-0.2462	0.4658	Sample et al. (1998b)
Selenium	-0.4158	0.3764	Sample et al. (1998b)
Zinc	4.3632	0.0706	Sample et al. (1998b)
2,3,7,8-TCDD	0.8113	1.0993	Sample et al. (1998b)

h, Pentachlorophenol concentration in small mammal tissue (mg/kg dry weight) calculated based on regression models, where [tissue] = 0.198 + 0.00452([$diet_{invertebrate}$])

i, USEPA (2005) assumes bioaccumulation of PAHs by birds and mammals is minimal due to rapid metabolism of these compounds after ingestion.

j, Small mammal tissue estimated based on the medial BAF for the general model presented in Sample et al. (1998b)

k, No value was identified in the literature; soil-to-small mammal BAF estimated based on the approach presented in Table 5, consistent with LANL (2017)

Table 4
Estimated Soil to Earthworm Bioaccumulation Factors (BAF) for Non-Ionic Organic Compounds
Draft Technical Memorandum: Proposed Wildlife Exposure Modeling Approach
Columbia Falls Aluminum Company
Columbia Falls, Montana

Analyte	K_{ow}: Octanol to water partitioning coefficient	K_{ww} : worm to soil water partitioning coefficient			K_{oc}: water to soil organic carbon partioning coefficient [c]				K_d: soil to water partitioning coefficient [d]	Soil to Earthworm BAF [e]

Notes:

a, log K_{ww} = 0.87*log K_{ow} - 2 (USEPA, 2007a; Jager, 1998)

b, Converted from wet weight to dry weight assuming 16% solids (USEPA, 2005; Jager, 1998)

c, K_{oc} values modeled based on regression equations from Gerstl (1990), for All Compounds: log K_{oc} = A*log K_{ow} + B, where A = slope and B = intercept.

d, K_d = f_{oc}*K_{oc}, where "foc" is the fraction of organic carbon in soil.

f_{oc} is assumed to be: 0.01

e, BAF = K_{ww} (L/kg worm dw) / K_d (L/kg soil dw)

f, log K_{ow} values obtained from EPI SUITE program, KOWWIN module v 1.69.

BAF, bioaccumulation factor
dw, dry weight
ww, wet weight

Notes:

a, $BAF_{soil\text{-}mammal}$ model based on LANL (2015) equation for Transfer Factor from soil to dry weight flesh (TF_flesh_dw):

$$BAF_{soil-mammal} = BAF_{beef} \times [\frac{(FIR_{MAX} \times BAF_{MAX\ plant/invert} + SIR_{MAX})}{(1-MC)}]$$

where:
$BAF_{soil\text{-}mammal\ dw}$ = Soil-to-small mammal BAF (kg soil, dw/kg flesh, $_{dw)}$
$BAF_{beef\ ww}$ = Diet-to-beef transfer factor (d/kg $beef_{ww}$)
$FIR_{MAX\ ww}$ = Maximum food ingestion rate for LANL prey species (0.305 kg $food_{ww}$/d; LANL, 2015)
$BAF_{MAXPlant/Invert}$ = Maximum BAF for plant or invertebrate dietary items of the prey species (kg $soil_{dw}$/kg $tissue_{ww}$)
SIR_{MAX} = Maximum incidental soil ingestion rate for LANL prey species (0.0193 kg $soil_{dw}$/d; LANL, 2015)
MC = Moisture content of flesh (assumed 68 percent per LANL, 2015)

b, Diet-to-beef transfer factor calculated based on RTI (2005), consistent with LANL (2017):

$$LogBAF_{beef\ ww} = Fat_{beef} \times (-0.099 \times \log K_{ow}{}^2 + 1.07 \times logKow - 3.56)$$

where:
$BAF_{beef\ ww}$ = Diet-to-beef transfer factor (d/kg $beef_{ww}$)
$Fat_{beef\ ww}$ = Fat content of beef; assumed to be 19 percent or 0.19 based on LANL (2017)
K_{ow} = Octanol-water partitioning coefficient

c, Assumed fat content of beef of 19 percent consistent with LANL (2017)
d, $BAF_{plant\ ww}$, Soil-to-plant bioaccumulation factor calculated on wet weight basis by multiplying the plant BAF in Table 3 by 1-moisture content of plant leaves (1 - 0.85 = 0.15 per LANL, 2017).
e, $BAF_{invert\ ww}$, Soil-to-invertebrate bioaccumulation factor calculated on wet weight basis by multiplying the plant BAF in Table 3 by 1-moisture content in soil invertebrates (1 - 0.61 = 0.39; LANL, 2017).
f, Maximum soil-to-tissue BAF between higher of the $BAF_{plant\ ww}$ and $BAF_{invert\ ww}$
BAF, bioaccumulation factor
dw, dry weight
ww, wet weight

Notes:

Maximum exposure point concentrations are example values to illustrate the calculation of COPEC concentrations in tissue; these values are not representative of exposure concentrations at the Site.

NA, Normalized BSAF was not applicable for metals

a, Normalized BSAF (kg OC / kg lipid) calculated based on K_{ow}, where BSAF = $K_{ow}^{-0.038}$ (DiToro and McGrath 2000)

b, For non-ionic organic constituents, dry weight BSAF calculated from sediment organic carbon and lipid normalized BSAF as follows:

$$BSAF_{dry\ weight} = BSAF_{norm} \times f_{lip;id} \times \frac{1}{f_{oc}}$$

where: $BSAF_{norm}$ = Normalized BSAF (kg OC/kg lipid)

f_{lipid} = Fraction of lipids in prey item expressed on a dry weight basis (0.065, invertebrates; 0.08, fish)

f_{oc} = Fraction of sediment organic carbon expressed on a dry weight basis (0.01 or 1.0%)

c, Median BSAF for non-depurated invertebrates determined by Bechtel-Jacobs (1998b)

BCF, bioconcentration factor

BSAF, biota-sediment accumulation factor

kg OC/kg lipid, kilogram organic carbon per kilogram lipid

Table 7
Avian and Mammalian Toxicity Reference Values
Draft Technical Memorandum: Proposed Wildlife Exposure Modeling Approach
Columbia Falls Aluminum Company
Columbia Falls, Montana

Analytes	Avian Receptors				Mammalian Receptors			
	Chronic TRV_{Low} [a] (mg/kg-bw/d)	Chronic TRV_{High} [b] (mg/kg-bw/d)	Test Animal	Source	Chronic TRV_{Low} [a] (mg/kg-bw/d)	Chronic TRV_{High} [b] (mg/kg-bw/d)	Test Animal	Source
Hexachlorocyclopentadiene	No TRV	No TRV	---	---	No TRV	No TRV	---	---
Hexachloroethane	No TRV	No TRV	---	---	No TRV	No TRV	---	---
Pentachlorophenol	6.73	52	geometric mean	USEPA (2007h); TechLaw (2008)	8.42	22.7	geometric mean	USEPA (2007h); TechLaw (2008)
Volatile Organic Compounds (VOCs)								
Methylcyclohexane	No TRV	No TRV	---	---	No TRV	No TRV	---	---
Dioxin/Furans								
2,3,7,8-TCDD	0.00000175	0.0000175	chicken	Sample et al (1996); Farmahin et al. (2012) [e]	0.000000562	0.00000376	geometric mean	Murray et al. (1979), as cited in LANL EcoRisk

Notes:
a, NOAEL is no observable adverse effects level.
b, LOAEL is low observable adverse effects level.
c, Aroclor 1254 used as a surrogate for Aroclor 1248 for both birds and mammals.
d, Di-n-butyl pthalate used as a surrogate for avian exposure to phthalates.
e, TRV based on the NOAEL for a ring-necked pheasant, divided by 8 based on the higher sensitivity of AHR1-dependent changes in gene expression of chickens and chicken-like birds, per Farmahin et al. (2012).
---, Appropriate data are not available from published literature to derive NOAEL and LOAEL values.
NA, Toxicity Reference Value not available.
bw/d, body weight per day.
TRV, toxicity reference value.
